Package ‘RnBeads’

March 17, 2015

Title  RnBeads

Description  Comprehensive analysis of DNA methylation data

Date  2015-03-17

Version  0.99.19

Suggests  BSgenome.Hsapiens.UCSC.hg19,
  BSgenome.Mmusrus.UCSC.mm10,
  BSgenome.Mmusrus.UCSC.mm9,
  BSgenome.Rnorvegicus.UCSC.rn5,

addDiffMethTable,RnBDiffMeth-method

Description
The values of options in RnBeads are stored in dedicated R objects accompanying the package. These objects are named `infos`, `accepted`, `current` and `previous`. They should not be loaded or otherwise operated on by users. Please refer to the documentation of `rnb.options` for accessing and modifying option values in RnBeads.

Format
`infos` is a `data.frame` containing information about all options in RnBeads. Row names in this table are the option names; the column names are "Type", "Named", "Null", "Max", "Min", "MaxInclusive" and "MinInclusive". `accepted` is a list containing the sets of accepted values for some of the options. `current` is a list with current values for all options. `previous` is a list with previous values for the affected options; this list is only temporarily used while setting option values through `rnb.options` or `rnb.xml2options`.

Author(s)
Yassen Assenov

addDiffMethTable,RnBDiffMeth-method

Description
Adds a differential methylation table

Usage
```r
## S4 method for signature 'RnBDiffMeth'
addDiffMethTable(object, dmt, comparison, region.type,
   grp.labs = c("group1", "group2"))
```

Arguments
- `object` RnBDiffMeth object
- `dmt` Differential methylation table to add
- `comparison` character or index of the comparison of the table to retrieve
- `region.type` character or index of the region type of the table to retrieve
- `grp.labs` character vector of length 2 specifying the names of the groups being compared

Value
the updated RnBDiffMeth object
Note

Caveat: if disk dumping is enabled the resulting object tables will be stored in the initial location of the object.

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols="Sample_Group", region.types="sample.groups <- rnb.sample.groups(rnb.set.example,"Sample_Group")[[1]]
dmt.sites <- computeDiffTab.extended.site(meth(rnb.set.example), sample.groups[[1]], sample.regions.to.sites <- regionMapping(rnb.set.example,"promoters")
dmt.promoters <- computeDiffTab.default.region(dmt.sites, map.regions.to.sites)
cmp.name <- get.comparisons(dm)[1]
grp.labs <- get.comparison.grouplabels(dm)[1,]
# add the promoter level differential methylation table
dm.add <- addDiffMethTable(dm, dmt.promoters, cmp.name,"promoters", grp.labs)
get.region.types(dm.add)

## End(Not run)
```

Description

Adds phenotypic or processing information to the sample annotation table of the given RnBSet object.

Usage

```r
## S4 method for signature 'RnBSet'
addPheno(object, trait, header)
```

Arguments

- **object**: RnBSet of interest.
- **trait**: Trait as a non-empty vector or factor. The length of this vector must be equal to the number of samples in object, the i-th element storing the value for the i-th sample. Note that names, if present, are ignored.
- **header**: Trait name given as a one-element character. This is the heading to be used for the sample annotation table. This method fails if such a trait already exists; in other words, if `header %in% names(phenotype(object))`. 

---

**addPheno, RnBSet-method**

`addPheno`
Value

The modified dataset as an object of type \texttt{RnBSet}.

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
is.hiPSC <- pheno(rnb.set.example)[, "Sample_Group"]=='hiPSC'
rnb.set.mod <- addPheno(rnb.set.example, is.hiPSC, "is_hiPSC")
pheno(rnb.set.mod)
## End(Not run)
```

Description

For the region annotation of a given \texttt{RnBSet} object. Subdivide each region into subsegments by hierarchical clustering on the site distances in a particular region and then splitting the region into subregions consisting of these site clusters. The number of clusters is determined in such way that the mean number of sites per cluster is given by the \texttt{ns} parameter.

Usage

```
addRegionSubsegments(rnb.set, annotation.dir, region.types = NULL,
add.region.types.to.options = FALSE, ns = 10)
```

Arguments

- \texttt{rnb.set} an \texttt{RnBSet} object
- \texttt{annotation.dir} a directory to save the annotation to for later reloading. (binary \texttt{RData} format.)
- \texttt{region.types} the region types to which subsegmentation should be applied. Must be a non-empty subset of \texttt{summarized.regions(rnb.set)}. Defaults (NULL) to all region types in \texttt{rnb.set}
- \texttt{add.region.types.to.options} Flag indicating whether to add the newly created subregions to the package’s \texttt{region.types} option
- \texttt{ns} the mean number of sites per cluster.

Value

the modified \texttt{RnBSet} object
annotation,RnBSet-method

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.set.mod <- addRegionSubsegments(rnb.set.example,tempdir(),region.types=c("tiling","genes"))
summary(meth(rnb.set.mod,type="tiling.subsegments"))
## End(Not run)
```
Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
## show present sites
head(annotation(rnb.set.example, add.names=TRUE))
## show promoters
ann.prom<-annotation(rnb.set.example, type="promoters", add.names=TRUE)
head(ann.prom)
## End(Not run)

append.cpg.stats  append.cpg.stats

Description

Appends additional metadata columns for CpG count and GC density to the specified regions.

Usage

append.cpg.stats(genome.data, regionlist)

Arguments

genome.data  Genome of interest.
regionlist  Genomic regions as a list of GRanges objects (or an object of type GRangesList), containing one set of regions per chromosome.

Value

The modified regionlist. Two columns are appended to the metadata of each element in this list - "CpG" and "GC". If the metadata already contains these columns, this function appends columns with similar names.

Author(s)

Yassen Assenov

as.RnBeadRawSet  as("MethyLumiSet", "RnBeadRawSet")

Description

Convert a MethyLumiSet object to RnBeadRawSet
Convert a RnBeadRawSet object to MethyLumiSet
assembly,RnBSet-method

Description

Extracts information about assembly

Usage

## S4 method for signature 'RnBSet'
assembly(object)

Arguments

object Dataset of interest.

Value

Sample annotation information available for the dataset in the form of a data.frame.

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
assembly(rnb.set.example) # "hg19"

## End(Not run)

auto.select.rank.cut

Description

automatically select a rank cutoff for given ranks and p-values current implementation: sort the p-values according to rank. select as rank cutoff the rank for which the worst (i.e. max) p-value in the top list is still smaller than the best (i.e. min) p-value of the group of worst-ranking p-values of equal size as the top-list

Usage

auto.select.rank.cut(p, r, alpha = 0.1)

Arguments

p vector of p-values
r vector of ranks
alpha the percentile to select the top and bottom part of the list
Value

the maximum rank fulfilling the criterion

Author(s)

Fabian Mueller

---

**BMIQ**

**BMIQ**

---

**Description**

Performs Beta-mixture quantile normalization, adjusting for type II bias in Infinium 450K data.

**Usage**

```r
BMIQ(beta.v, design.v, doH = TRUE, nfit = 50000, th1.v = c(0.2, 0.75),
th2.v = NULL, niter = 5, tol = 0.001)
```

**Arguments**

- **beta.v** double vector consisting of beta values. Missing values (NAs) cannot be handled, so these must be removed or imputed prior to running BMIQ. Before normalization, beta values that are exactly 0 and exactly 1 are replaced by the minimum positive and maximum value below 1, respectively.

- **design.v** integer vector of length `length(beta.v)`, containing the values 1 and 2 only. These values specify probe design type.

- **doH** Flag indicating if normalization for hemimethylated type II probes is to be performed.

- **nfit** Number of probes of a given design to use for the fitting. Smaller values will make BMIQ faster at the expense of accuracy. Values between 10000 and 50000 seem to work well.

- **th1.v** Thresholds "type 1" to use for the initialization of the EM algorithm. These values should represent best guesses for calling type I probes hemi-methylated and methylated, and are refined in further steps by the algorithm.

- **th2.v** Thresholds "type 2" to used for the initialization of the EM algorithm. These values should represent best guesses for calling type II probes hemi-methylated and methylated, and are refined in further steps by the EM algorithm. If this is NULL (default), the thresholds are estimated based on `th1.v` and a modified PBC correction method.

- **niter** Maximum number of EM iterations to be performed.

- **tol** Tolerance threshold for EM algorithm.
Value

List with the following elements:

"all"  The normalised beta-profile for the sample.
"class1"  Methylation state assigned to the type I probes.
"class2"  Methylation state assigned to the type II probes.
"av1"  Mean beta values for the \( nL \) classes for type I probes.
"av2"  Mean beta values for the \( nL \) classes for type II probes.
"hf"  Hubble dilation factor.
"th1"  Estimated thresholds used for type I probes.
"th2"  Estimated thresholds used for type II probes.

Author(s)

Andrew Teschendorff and Steve Horvath; with minor modifications by Yassen Assenov

ClusterArchitecture-class

ClusterArchitecture Class

Description

A virtual class for storing specifications of architectures for different compute clusters. It is designed to let other classes inherit from it.

Details

For a concrete child class for a sun grid architecture specification see ClusterArchitectureSGE.

If you want to implement your own child class be sure to at least implement the following functions: getSubCmdTokens,ClusterArchitecture-method.

Slots

name  A name or identifier
executables  A NAMED character vector of executables that can be used by the cluster. For instance, the \( \mathbb{R} \) executable is important
getSubCmdTokens.optional.args  character vector containing the valid optional arguments to the getSubCmdTokens,ClusterArchitecture-method function.

Methods

getSubCmdTokens,ClusterArchitecture-method  Returns a vector of command line tokens corresponding to submitting a job with the given command to the cluster.
getSubCmdStr,ClusterArchitecture-method  Returns a string for the command line corresponding to submitting a job with the given command to the cluster.
setExecutable,ClusterArchitecture,character,character-method  Tells the cluster architecture about an executable that can be submitted as job.
getExecutable,ClusterArchitecture,character-method  Gets the location of an executable associated with a name.
Author(s)

Fabian Mueller

---

**ClusterArchitectureSGE-class**

*ClusterArchitectureSGE Class*

---

**Description**

A child class of `ClusterArchitecture` implementing specifications of Sun Grid Engine (SGE) architectures.

**Details**

Follow this template if you want to create your own ClusterArchitecture class.

**Slots**

see `ClusterArchitecture`

**Methods**

`getSubCmdTokens, ClusterArchitectureSGE-method` Returns a vector of command line tokens corresponding to submitting a job with the given command to the cluster

Author(s)

Fabian Mueller

---

**coercion-methods**

`as("RnBeadSet", "MethyLumiSet")`

---

**Description**

Convert a `RnBeadSet` object to `MethyLumiSet`
Description

Combine two objects inheriting from RnBSet class.

Usage

```r
## S4 method for signature 'RnBSet,RnBSet'
combine(x, y)
```

Arguments

- `x,y` RnBeadSet, RnBeadRawSet or RnBiseqSet object

Details

The sample sets of `x` and `y` should be unique. Sample annotation information is merged only for columns which have identical names in both objects. CpG sites of the new object are a union of those present in both objects.

Value

Combined RnBeadSet, RnBeadRawSet or RnBiseqSet object

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
r1 <- rnb.set.example
r1 <- remove.samples(r1,samples(rnb.set.example)[1:5])
i <- which(r1@sites[,2] == 15 | r1@sites[,2] == 21)
sites.rem.r1 <- union(sample(1:nrow(meth(rnb.set.example)),500),i)
r1 <- remove.sites(r1,sites.rem.r1)
r2 <- rnb.set.example
r2 <- remove.samples(r2,samples(rnb.set.example)[6:12])
sites.rem.r2 <- sample(1:nrow(meth(rnb.set.example)),800)
r2 <- remove.sites(r2,sites.rem.r2)
rc <- combine(r1,r2)
#assertion: check the number of sites
sites.rem.c <- intersect(sites.rem.r1,sites.rem.r2)
(nrow(meth(rnb.set.example))-length(sites.rem.c)) == nrow(meth(rc))
## End(Not run)
```
**combine.diffMeth.objs**

**Description**

Combine differential methylation objects (output from `rnb.run.differential`). To be more precise, the `diffmeth` and `dm.enrich` are merged. Individual objects that are merged are assumed to belong to the same analysis and vary only in their indexing of region types and comparisons.

**Usage**

```r
combine.diffMeth.objs(obj.list)
```

**Arguments**

- `obj.list`: A list containing outputs from `rnb.run.differential`.

**Author(s)**

Fabian Mueller

---

**combineTestPvalsMeth**

**Description**

**Usage**

```r
combineTestPvalsMeth(pvalues, testWeights = NULL, correlated = FALSE, methExpectedTestCorrelation = 0.8)
```

**Arguments**

- `pvalues`: P-values to combine.
- `testWeights`: Weights for the individual tests.
- `correlated`: Are the individual tests correlated?
- `methExpectedTestCorrelation`: Expected correlation. Empirically approximated to the default value of 0.8 for DNA-methylation.
computes a difference table containing multiple difference measures. In the simple version the mean of the difference in means, the mean quotient in means and a combination of p-values on the site level are computed. This is computed for each row of the input table. The extended version contains additional columns.

Usage

computeDiffTab.default.region(dmtp, regions2sites, includeCovg = FALSE)

Arguments

dmtp differential methylation table on the site level (as obtained from computeDiffTab.default.site)
regions2sites a list containing for each region the indices of the corresponding sites in the site differential methylation table
includeCovg flag indicating whether to include coverage information

Value

a dataframe containing the following variables for a given genomic region:

mean.mean.g1, mean.mean.g2
mean mean methylation levels for group 1 and 2 across all sites in a region

mean.mean.diff
Mean difference in means across all sites in a region

mean.mean.quot.log2
Mean quotient in means across all sites in a region

comb.p.val Combined p-value using a generalization of Fisher's method. See combineTestPvalsMeth for details.
computeDiffTab.default.site

comb.p.adj.fdr
   FDR adjusted combined p-value
num.sites    number of sites that were considered for a region
mean.num.na.g1/2
   mean number (across all considered sites) of samples that contained an NA for
group 1 and 2 respectively
mean.mean.covg.g1/2
   Mean value of mean coverage values (across all samples in a group) across all
sites in a region
mean.nsamples.covg.thresh.g1/2
   mean number (across all considered sites) of samples that have a coverage
larger than the specified threshold (see computeDiffTab.default.site
for details) for group 1 and 2 respectively

Author(s)
   Fabian Mueller

Examples
   ## Not run:
   library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
meth.mat <- meth(rnb.set.example)
sample.groups <- rnb.sample.groups(rnb.set.example)[[1]]
dm.sites <- computeDiffTab.extended.site(meth.mat,sample.groups[[1]],sample.groups[[2]])
map.regions.to.sites <- regionMapping(rnb.set.example,"promoters")
dm.promoters <- computeDiffTab.default.region(dm.sites,map.regions.to.sites)

   ## End(Not run)

computeDiffTab.default.site
   computeDiffTab.site

Description
   computes a difference table containing multiple difference measures, In the simple version the dif-
ference in means, quotients in means and a p-value for the comparison of two groups in a table
are computed. This is computed for each row of the input table. The extended version contains
additional columns

Usage
   computeDiffTab.default.site(X, inds.g1, inds.g2,
   diff.method = rnb.getOption("differential.site.test.method"),
   paired = FALSE, adjustment.table = NULL, eps = 0.01)
   computeDiffTab.extended.site(X, inds.g1, inds.g2,
   diff.method = rnb.getOption("differential.site.test.method"),
   paired = FALSE, adjustment.table = NULL, eps = 0.01, covg = NULL,
   covg.thres = rnb.getOption("filtering.coverage.threshold"))
Arguments

X Matrix on which the difference measures are calculated for every row
inds.gl column indices of group 1 members
inds.g2 column indices of group 2 members
diff.method Method to determine p-values for differential methylation. Currently supported are "ttest" for a two-sided Welch t-test, "refFreeEWAS" for adjusting for cell mixtures, and "limma" for p-values resulting from linear modeling of the transformed beta values (M-values) and using techniques from expression microarray analysis employed in the limma package.
paired should a paired analysis be performed. If TRUE then inds.g1 and inds.g2 should have exactly the same length and should be order, such that the first element of inds.g1 corresponds to the first element of inds.g2 and so on.
adjustment.table a table of variables to be adjusted for in the differential methylation test. Currently this is only supported for diff.method="limma"
eps Epsilon for computing quotients (avoid division by 0 by adding this value to denominator and enumerator before calculating the quotient)
covg coverage information (should be NULL for disabled or of equal dimensions as X)
covg.thres a coverage threshold

Value

a dataframe containing the following variables:
mean.g1 Mean of group 1
mean.g2 Mean of group 2
mean.diff Difference in means
mean.quot.log2 log2 of the quotient of means
diffmeth.p.val P-value (as determined by diff.method)
max.g1/max.g2 [extended version only] Group maxima
min.g1/min.g2 [extended version only] Group minima
sd.g1/sd.g2 [extended version only] Group standard deviations
min.diff [extended version only] Minimum of 0 and single linkage difference between the groups
diffmeth.p.adj.fdr [extended version only] FDR adjusted p-values
num.na.g1/num.na.g2 [extended version only] number of NA methylation values for groups 1 and 2 respectively
mean.covg.g1/mean.covg.g2 [extended version with coverage information only] mean coverage of groups 1 and 2 respectively
min.covg.g1/min.covg.g2
[extended version with coverage information only] minimum coverage of groups 1 and 2 respectively
max.covg.g1/max.covg.g2
[extended version with coverage information only] maximum coverage of groups 1 and 2 respectively
covg.thresh.nsamples.g1/2
[extended version with coverage information only] number of samples in group 1 and 2 respectively exceeding the coverage threshold for this site.

Author(s)
Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
 meth.mat <- meth(rnb.set.example)
sample.groups <- rnb.sample.groups(rnb.set.example)[[1]]
dm <- computeDiffTab.extended.site(meth.mat, sample.groups[[1]], sample.groups[[2]])
summary(dm)
## End(Not run)
```

---

covg,RnBSet-method  covg-methods

Description
Extract coverage information from an object of RnBSet class.

Usage
```r
## S4 method for signature 'RnBSet'
covg(object, type = "sites", row.names = FALSE)
```

Arguments
- **object**: Dataset of interest.
- **type**: `character` singleton. If `sites` DNA methylation information per each available site is returned. Otherwise should be one of region types for for which the summarized coverage information is available.
- **row.names**: Flag indicating of row names are to be generated in the result.

Value
Coverage information available for the dataset in the form of a matrix.
create.densityScatter

Examples

```
## Not run:
library(RnBeads.hg19)
data(small.example.object)
## per-site beta-value matrix
cvg<-cavg(rnb.set.example, row.names=TRUE)
head(cvg)

## End(Not run)
```

describe.densityScatter

describe.densityScatter
describe.densityScatter

Description

Creates a density scatterplot highlighting points in sparsely populated plot regions as well as points marked as special in a separate color

Usage

```
create.densityScatter(df2p, is.special = NULL, dens.subsample = FALSE,
dens.special = TRUE, sparse.points = 0.01, dens.n = 100,
add.text.cor = FALSE)
```

Arguments

- `df2p` data.frame to be plotted. Only the fist two columns are taken into account as x and y coordinates respectively
- `is.special` boolean vector of length equal to the number of rows in `df2p`. Specifies which points should be highlighted separately in a different color
- `dens.subsample` if the number of points exceeds this number, subsample the number of points for the density estimation to that number. Any non-numeric value disables subsampling.
- `dens.special` Flag indicating whether the points of the special population should be colored according to their density
- `sparse.points` Either percentage (<=1, >=0) or the absolute number of points in the sparsely populated area that should be drawn separately. A value of 0 means that these points will not be drawn.
- `dens.n` passed on to `ggplot2::stat_density2d` argument: n
- `add.text.cor` flag indicating whether a text token with the correlation coefficient should be included in the lower right corner of the plot

Value

`ggplot` object
create.hex.summary.plot

Author(s)

Fabian Mueller

Examples

```r
## Not run:
d <- data.frame(x=rnorm(1000),y=rnorm(1000))
s <- rep(FALSE,1000)
s[sample(1:length(s),100)] <- TRUE
create.densityScatter(d,s)

## End(Not run)
```

create.hex.summary.plot

Description

Creates a summary plot binning the data given by a certain quantity in heagonal bins

Usage

```r
create.hex.summary.plot(df2p, x = colnames(df2p)[1], y = colnames(df2p)[2],
q = colnames(df2p)[3], bins = 128, fun = median, ...)
```

Arguments

- `df2p`  
data.frame to be plotted.
- `x`  
name of the variable in `df2p` considered as x-axis
- `y`  
name of the variable in `df2p` considered as y-axis
- `q`  
name of the variable in `df2p` considered as quantity to be summarized over bins
- `bins, fun, ...`  
arguments to be passed on to `stat_summary_hex`

Value

`ggplot` object

Author(s)

Fabian Mueller
create.scatter.dens.points

Description

Creates a scatterplot containing all points in a given data.frame. Points are colored according to point density. Optionally, a selection of points are shown in a different color.

Usage

```r
create.scatter.dens.points(df2p, is.special = NULL, dens.special = TRUE, mock = FALSE)
```

Arguments

df2p    data.frame to be plotted. Only the first two columns are taken into account as x and y coordinates respectively.

is.special boolean vector of length equal to the number of rows in df2p. Specifies which points should be highlighted separately in a different color.

dens.special Flag indicating whether the points of the special population should be colored according to their density.

mock Should only the axis be plotted? useful when exporting scatterplots with lots of points as image and the corresponding axis as vector graphics.

Value

ggplot object

Author(s)

Fabian Mueller

Examples

```r
## Not run:
d <- data.frame(x=rnorm(1000), y=rnorm(1000))
s <- rep(FALSE, 1000)
s[sample(1:length(s), 100)] <- TRUE
create.scatter.dens.points(d, s)
## End(Not run)
```
createReport

Description

Creates a new report object.

Usage

createReport(fname, title, page.title = "RnBeads report", authors = NULL,
dirs = NULL, init.configuration = FALSE)

Arguments

fname  Single-element character vector denoting the name of the file to contain the HTML report. If this file already exists, it will be overwritten.
title  Title of the report in the form of a single-element character vector.
page.title  Web page title. This usually appears in the web browser’s window title when the report is open. If specified, this must be a vector. Note that only the first element is used.
authors  Optional list of authors in the form of a character vector. This list is included in the header of the generated HTML file. Note that author names can contain only Latin letters, space, dash (-), comma (,) or dot (.).
dirs  Location of the supporting directories, that is, paths that are expected to contain additional files linked to from the HTML report. See the Details section for a list of these directories.
init.configuration  Flag indicating if the report configuration data should be initialized. If this parameter is TRUE, the method creates the respective directory and copies configuration files that define cascading style sheet (CSS) definitions and Javascript functions used by the HTML report. If such configuration files already exist, they will be overwritten. Since the aforementioned files can be shared by multiple reports, it is recommended that the configuration is initialized using the method rnb.initialize.reports, instead of setting this flag to TRUE.

Details

If specified, the parameter dirs must be a character vector. The following names are read:

- "configuration" Directory that contains the auxiliary configuration files, such as style sheets and Javascript files. If missing or NA, the default value used is "configuration".
- "data" Directory to contain the tables, lists and other generated data files that are linked to in the HTML report. If missing or NA, the value used is formed from the file name fname (without the extension) and the suffix "_data".
- "pngs" Directory to contain the low resolution PNG images shown in the HTML report. If missing or NA, the value used is formed from the file name fname (without the extension) and the suffix "_images".
- "pdfs" Directory to contain the PDF images (if such are created). If not missing or NA, the value used is formed from the file name fname (without the extension) and the suffix "_pdf".
"high" Directory to contain the high resolution PNG images (if such are created). If missing or NA, the value used is the same as the `pngs` directory. Any other elements, if present, are ignored. Note that these directories are not required to point to different locations. In particular, if the directories for low and for high resolution images are identical, the high-resolution image files are assumed to be the ones with suffix "\_high\_resolution.png". See `createReportPlot` for creating image files. In order to ensure independence of the operating system, there are strong restrictions on the names of the file and directories. The name of the report’s HTML file can consist of the following symbols only: Latin letters, digits, dot (.), dash (-) and underline (_). The extension of the report’s HTML file must be one of htm, html, xhtml or xml. The supporting directories must be given as relative paths; the restrictions on the path names are identical to the ones for file name. Forward slash (/) is to be used as path separator. Path names cannot start or end with a slash. None of the directory names can be an empty string, use "." instead. A value in the form "\_mypath/\_.html" for `fname` is invalid. Upon initialization, the report attempts to create or overwrite the specified `fname`. If the path to it does not exist, or if the current process does not have permissions to write to the file, report initialization will fail. The report object visits each supporting directory (except configuration) and attempts to create it, unless it is an existing empty directory. Report initialization will fail if any of the visited directories does not meet the criteria and could not be created. Hidden files (file names starting with "." on Unix platforms) are ignored. Thus, all supporting directories that already exist and contain hidden files only are considered valid.

Value

Newly created Report object.

createReportGgPlot

createReportGgPlot

Description

creates a report plot containing a ggplot object. Except for the `ggp` parameter, the signature and behavior is identical to `createReportPlot`

Usage

```r
createReportGgPlot(ggp, fname, report = NULL, width = 7, height = 7,
create.pdf = TRUE, low.png = as.integer(100), high.png = as.integer(0))
```
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ggp</td>
<td>ggplot object to be plotted</td>
</tr>
<tr>
<td>fname</td>
<td>character vector with one element storing the name of the output file, without the extension. The initialized object appends <code>.pdf</code> and/or <code>.png</code> to this name.</td>
</tr>
<tr>
<td>report</td>
<td>Report (object of type <code>Report</code>) to which this plot is going to be added. This is used to set the directories for PDF and/or PNG files generated for these plots. If this parameter is <code>NULL</code>, the current working directory is used to host all generated images.</td>

createReportPlot  
createReportPlot

Description

Initializes a report plot and opens a device to create it. The type of the device created depends on the parameters `create.pdf`, `low.png` and `high.png`. If `create.pdf` is `TRUE`, a PDF device is opened and its contents are later copied to PNG device(s) if needed. Otherwise, a PNG device is opened. Note that at least one of the following conditions must be met:

- `create.pdf == TRUE`
- `low.png > 0`
- `high.png > 0`

Usage

```r
createReportPlot(fname, report = NULL, width = 7, height = 7, create.pdf = TRUE, low.png = 100L, high.png = 0L)
```
createReportPlot

Arguments

fname character vector with one element storing the name of the output file, without the extension. The initialized object appends .pdf and/or .png to this name.

report Report (object of type Report) to which this plot is going to be added. This is used to set the directories for PDF and/or PNG files generated for these plots. If this parameter is NULL, the current working directory is used to host all generated images.

width numeric storing the width of the device in inches. The length of this vector must be 1.

height numeric storing the height of the device in inches. The length of this vector must be 1.

create.pdf Flag indicating if a PDF image is to be created. The length of this vector must be 1.

low.png Resolution, in dots per inch, used for the figure image. Set this to 0 or a negative value to disable the creation of a low resolution image. The length of this vector must be 1.

high.png Resolution, in dots per inch, used for a dedicated image. Set this to 0 or a negative value to disable the creation of a high resolution image. The length of this vector must be 1.

Details

In order to ensure independence of the operating system, there are strong restrictions on the name of the file. It can consist of the following symbols only: Latin letters, digits, dot (.), dash (–) and underline (_). The name must not include paths, that is, slash (/) or backslash (\) cannot be used.

Value

Newly created ReportPlot object.

Author(s)

Yassen Assenov

pdf for manually initializing a graphics device; Report for other functions adding contents to an HTML report

Examples

```R
## Not run:
plot.image <- createReportPlot('scatterplot_tumors')
plot(x = c(0.4, 1), y = c(9, 3), type = 'p', main = NA, xlab = expression(beta), ylab = 'Measure')
off(plot.image)
## End(Not run)
```
data.frame2GRanges  

**Description**  
Converts a data.frame that defines genomic regions to object of type GRanges.

**Usage**

```r  
data.frame2GRanges(dframe, ids = rownames(dframe),  
  chrom.column = "chromosome", start.column = "start", end.column = "end",  
  strand.column = NULL, assembly = "hg19", sort.result = TRUE)  
```

**Arguments**

- **dframe**  
  Table defining genomic regions.
- **ids**  
  Region names (identifiers) as a character vector, or NULL if no names are present.
- **chrom.column**  
  Column name or index that lists the chromosome names.
- **start.column**  
  Column name or index that lists the start positions of the regions.
- **end.column**  
  Column name or index that lists the end positions of the regions.
- **strand.column**  
  Column name or index that lists the strands on which the regions are located. Set this to NULL if this region set is not strand-specific.
- **assembly**  
  Genome assembly of interest. See `rnb.get.assemblies` for the list of supported genomes.
- **sort.result**  
  Should the resulting table be sorted

**Value**

GRanges object encapsulating all well defined regions on supported chromosomes, contained in dframe. Columns other that the ones listed as parameters in this function are included as metadata.

**Author(s)**

Yassen Assenov

densRanks  

**Description**

Rank the points accordind to density of the region they fall in. Densities are computed as Kernel Density estimates. The method and parameters are implemented in analogy to `grDevices::densCols`

**Usage**

```r  
densRanks(x, y = NULL, nbin = 128, bandwidth)  
```
**Arguments**

- `x`: x-coordinate
- `y`: y-coordinate
- `nbin`: number of bins
- `bandwidth`: bandwidth

**Author(s)**

Fabian Mueller

---

**Description**

remove tables stored to disk from the file system. Useful for cleaning up disk dumped objects. **CAUTION:** currently only works with reloaded objects.

**Usage**

```r
## S4 method for signature 'RnBDiffMeth'
destroy(object)
```

**Arguments**

- `object`: `RnBDiffMeth` object

**Value**

Nothing of particular interest

**Author(s)**

Fabian Mueller

---

**Description**

Remove tables stored to disk from the file system. Useful for cleaning up disk dumped objects.
deviation.plot.beta

Usage

## S4 method for signature 'RnBSet'
destroy(object)

## S4 method for signature 'RnBeadRawSet'
destroy(object)

## S4 method for signature 'RnBeadSet'
destroy(object)

Arguments

object object inheriting from RnSet

Value

Nothing of particular interest

Description

Creates a deviation plot based on the methylation beta values of a population.

Usage

deviation.plot.beta(betas, c.values = NULL, c.legend = NULL)

Arguments

betas Non-empty numeric matrix of methylation beta values. Rows in this matrix must denote sites or regions, and columns - samples. If a locus (row in the matrix) contains missing values only, it is not included in the plot.

c.values Vector (usually a factor) storing category or quantitative values for each site or region. The length of this vector must be equal to nrow(betas), the i-th element storing the property values for the i-th locus in betas. Note that this vector’s names, if present, are ignored.

c.legend If c.values stores categories, this parameter specifies the mapping from property values to colors. The mapping is in the form of a named character vector. All values that appear in c.values must be present among the names of this vector. The order of the values in this mapping determines in which order the colors are stacked (when the number of loci is large). If c.values denotes a quantitative measure, this parameter is a singleton integer, specifying the color scheme for visualizing the values. Currently, the only supported values are 2 and 3. See rnb.options for more details.
Value

Methylation variability as a number between 0 and 1, invisibly. This number denotes the relative area of variation in the generated plot.

Author(s)

Yassen Assenov

Description

Extract detection p-values from an object of RnBeadSet class.

Usage

```r
## S4 method for signature 'RnBeadSet'
dpval(object, type = "sites", row.names = FALSE)
```

Arguments

- `object`: RnBeadSet or RnBeadRawSet object
- `type`: character singleton. If `sites` detection p-values per each available site is returned. Otherwise should be one of region types for for which the summarized p-values are available
- `row.names`: Flag indicating of row names are to be generated in the result.

Value

detection p-values available for the dataset in the form of a matrix.

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
dp<-dpval(rnb.set.example, row.names=TRUE)
head(dp)
## End(Not run)
```
estimateProportionsCP

**Description**
Estimates cell type proportions using the constrained projection method from Houseman et al. [1]

**Usage**
```r
estimateProportionsCP(rnb.set, cell.type.column, n.most.variable = NA, n.markers = 500L, constrained = TRUE, full.output = FALSE)
```

**Arguments**
- `rnb.set`: RnBSet object
- `cell.type.column`: integer index or character identifier of a column in the RnBSet object sample annotation table which gives the mapping to reference cell type samples
- `n.most.variable`: singleton integer specifying how many top variable CpGs should be used for marker selection. If NA all the sites are considered (take into account extended computation times).
- `n.markers`: singleton integer specifying how many CpGs should be used as markers for fitting the projection model
- `constrained`: if TRUE the returned cell type proportion estimates are non-negative
- `full.output`: if TRUE not only the estimated proportions but also the intermediate analysis results are returned

**Details**
The column specified by `cell.type.column` should give assignment of each reference sample to a cell type and missing values for all the target samples. First the marker selection model is fit to estimate association of each CpG with the given reference cell types (first expression in eq. (1) of [1]). The strength of association is expressed as an F-statistic. Since fitting the marker selection model to all CpGs can take a lot of time, one can limit the marker search only to variable CpG positions by setting `n.most.variable` to non-NA positive integer. The CpGs will be ranked by decreasing across-sample variance in the reference data set and `n.most.variable` will be taken to fit the marker selection model. Coefficients of the fit together with the F-statistic value for each CpG are returned in case `full.output` is TRUE. Thereafter, `n.markers` are selected as true quantitative markers and the projection model (eq. [2]) is fit to estimate contributions of each cell type. Depending on the value of `constrained` the returned coefficients can be either raw or enforced to attain values between 0 and 1 with within-sample sum less or equal to 1.

**Value**
a matrix of estimated cell type contributions (samples times cell types) or a list with results of the intermediate steps (see details).
Note

Requires the package \texttt{nlme}.

Author(s)

Pavlo Lutsik

References

Description

export differentially methylated regions to region file (standard bed). The output is in BED6 format where the score corresponds to the combined rank (rank==1 would receive a score of 1000 and a combined rank equal to the number of regions a score of 0)

Usage

\hspace{1em} \texttt{exportDMRs2regionFile} (rnbSet, diffmeth, dest, comp.name, region.type, rank.cut = NULL, rerank = FALSE)

Arguments

- \texttt{rnbSet} \hspace{1em} the RnBSet object for which the DMRs were computed.
- \texttt{diffmeth} \hspace{1em} DiffMeth object. See \texttt{rnb.execute.computeDiffMeth} for details.
- \texttt{dest} \hspace{1em} destination file name
- \texttt{comp.name} \hspace{1em} name of the comparison
- \texttt{region.type} \hspace{1em} region type.
- \texttt{rank.cut} \hspace{1em} rank cutoff. If \texttt{NULL} (default), all regions are processed.
- \texttt{rerank} \hspace{1em} flag indicating whether the ranks should be reranked or whether \texttt{rank.cut} refers to the absolute rank

Value

\hspace{1em} NULL

Author(s)

Fabian Mueller
Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example,pheno.cols=c("Sample_Group","Treatment")
exportDMRs2regionFile(rnb.set.example, dm, tempfile(), get.comparisons(dm)[1], "promoters")
## End(Not run)
```

get.adjustment.variables

Description

Given indices for two groups of samples for comparison, this function retrieves a data.frame containing the variables to be adjusted for

Usage

```r
get.adjustment.variables(rnbSet, inds.g1, inds.g2 = -inds.g1,
colnames.adj = c(), colname.target = "", adjust.sva = FALSE,
adjust.celltype = FALSE)
```

Arguments

- `rnbSet` RnBSet object
- `inds.g1` sample indices in `rnbSet` of group 1 members
- `inds.g2` sample indices in `rnbSet` of group 2 members
- `colnames.adj` column names in `pheno(rnbSet)` to retrieve
- `colname.target` column names in `pheno(rnbSet)` of the target variable. Only important if `adjust.sva==TRUE`
- `adjust.sva` flag indicating whether the resulting table should also contain surrogate variables (SVs) for the given target variable.
- `adjust.celltype` flag indicating whether the resulting table should also contain estimated celltype contributions. See `rnb.execute.ct.estimation` for details.

Value

a data.frame containing one column for each selected variable from the phenotypic data each row corresponds to a sample in the union of samples of the two groups with the first `length(inds.g1)` rows corresponding to group 1 and the remaining rows corresponding to group 2

Author(s)

Fabian Mueller
get.comparison.grouplabels,RnBDiffMeth-method

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
sample.groups <- rnb.sample.groups(rnb.set.example)[[1]]
get.adjustment.variables(rnb.set.example,sample.groups[[1]],sample.groups[[2]],"Cell_Line")

## End(Not run)
```

get.comparison.grouplabels,RnBDiffMeth-method  
get.comparison.grouplabels-methods

Description

Gets all comparison grouplabels represented in the object as character matrix of dimension n.comparisons x 2 where the columns specify group names 1 and 2 respectively

Usage

```r
## S4 method for signature 'RnBDiffMeth'
get.comparison.grouplabels(object)
```

Arguments

- `object` RnBDiffMeth object

Value

character matrix containing comparison group names

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example,pheno.cols=c("Sample_Group","Treatment")
get.comparison.grouplabels(dm)

## End(Not run)
```
get.comparison.info

get.comparison.groupsizes,RnBDiffMeth-method
get.comparison.groupsizes-methods

Description

Gets all comparison group sizes represented in the object as character matrix of dimension n.comparisons x 2 where the columns specify sizes of groups 1 and 2 respectively

Usage

## S4 method for signature 'RnBDiffMeth'
get.comparison.groupsizes(object)

Arguments

object RnBDiffMeth object

Value

character matrix containing comparison group sizes

Author(s)

Fabian Mueller

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example,pheno.cols=c("Sample_Group","Treatment")
get.comparison.groupsizes(dm)

## End(Not run)

get.comparison.info

get.comparison.info

Description

retrieve the comparison information for an RnBSet object
Usage

get.comparison.info(x,
    pheno.cols = rnb.getOption("differential.comparison.columns"),
    region.types = rnb.region.types.for.analysis(x),
    pheno.cols.all.pairwise = rnb.getOption("differential.comparison.columns.all.pairwise"),
    columns.pairs = rnb.getOption("columns.pairing"),
    columns.adj = rnb.getOption("covariate.adjustment.columns"),
    adjust.sva = rnb.getOption("differential.adjustment.sva"),
    pheno.cols.adjust.sva = rnb.getOption("inference.targets.sva"),
    adjust.celltype = rnb.getOption("differential.adjustment.celltype"),
    adjust.na.rm = TRUE)

Arguments

x \hspace{1cm} \text{RnBSet object}
pheno.cols \hspace{1cm} \text{column names of the pheno slot in x on which the dataset should be partitioned. Those columns are required to be factors or logical. In case of factors, each group in turn will be compared to all other groups}
region.types \hspace{1cm} \text{which region types should be processed for differential methylation}
pheno.cols.all.pairwise \hspace{1cm} \text{integer or character vector specifying the columns of pheno(x) on which all pairwise comparisons should be conducted. A value of NULL indicates no columns.}
columns.pairs \hspace{1cm} \text{argument passed on to rnb.sample.groups. See its documentation for details.}
columns.adj \hspace{1cm} \text{Column names or indices in the table of phenotypic information to be used for confounder adjustment in the differential methylation analysis.}
adjust.sva \hspace{1cm} \text{flag indicating whether the adjustment table should also contain surrogate variables (SVs) for the given target variable.}
pheno.cols.adjust.sva \hspace{1cm} \text{Target variables for SVA adjustment. Only important if adjust.sva==TRUE. Only the intersection of pheno.cols and pheno.cols.adjust.sva is considered for SVA adjustment.}
adjust.celltype \hspace{1cm} \text{flag indicating whether the resulting table should also contain estimated celltype contributions. See rnb.execute.ct.estimation for details.}
adjust.na.rm \hspace{1cm} \text{Flag indicating whether NAs in the adjustment table should be removed.}

Value

a list containing one element for each comparison to be conducted. Each element is again a list containing:

comparison \hspace{1cm} \text{the name of the comparison}
pheno.colname \hspace{1cm} \text{the column name of the sample annotation table the comparison is derived from}
group.names \hspace{1cm} \text{the names of the two groups being compared}
group.inds \hspace{1cm} \text{the sample indices of the samples belonging to the two groups}
paired flag indicating whether paired analysis is conducted
adj.sva flag indicating whether adjustment for SVA is conducted
adj.celltype flag indicating whether adjustment for cell type is conducted
adjustment.table the covariate adjustment table. NULL if the comparison is not adjusted
region.types the region types applicable to the analysis

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)

cmp.info <- get.comparison.info(rnb.set.example,pheno.cols=c("Sample_Group","Treatment"))
cmp.info[[1]]

## End(Not run)
```

get.comparisons,RnBDiffMeth-method

get.comparisons-methods

Description

Gets all comparisons represented in the object as character vector

Usage

```r
## S4 method for signature 'RnBDiffMeth'
get.comparisons(object)
```

Arguments

- `object` RnBDiffMeth object

Value

character vector containing comparisons

Author(s)

Fabian Mueller
### Examples
```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Sample_Group","Treatment"))
get.comparisons(dm)
## End(Not run)
```

### Description
Retrieves an NxK matrix of cell type contributions stored in an RnBSet for a given target variable

### Usage
```r
get.covariates.ct(rnb.set)
```

### Arguments
- `rnb.set`: RnBSet object

### Value
an NxK matrix of K cell types contributions for N samples of the rnb.set. NULL if the components have not been computed or added to rnb.set.

### Description
Retrieves an NxK table of Surrogate variables stored in an RnBSet for a given target variable

### Usage
```r
get.covariates.sva(rnb.set, target)
```

### Arguments
- `rnb.set`: RnBSet object
- `target`: target variable. Must be in `pheno(rnb.set)` and belong to target variables for which the SVs have already been computed and stored in the RnBSet.

### Value
an NxK table of K Surrogate variables stored for N samples of the rnb.set. NULL if the components have not been computed or added to rnb.set.
get.covg.thres,RnBDiffMeth-method

get.covg.thres-methods

Description

Gets the coverage threshold employed for obtaining statistics in the differential methylation tables.

Usage

## S4 method for signature 'RnBDiffMeth'
get.covg.thres(object)

Arguments

object RnBDiffMeth object

Value

integer coverage threshold

Author(s)

Fabian Mueller

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
sva.obj <- rnb.execute.sva(rnb.set.example,c("Sample_Group","Treatment"),numSVmethod="be"
sva.obj$sva.performed
sva.obj$num.components
rnb.set.mod <- set.covariates.sva(rnb.set.example, sva.obj)
gget.covariates.sva(rnb.set.mod,"Sample_Group")

## End(Not run)
get.cpg.stats

Description
Computes CpG-related statistics for the specified regions.

Usage
get.cpg.stats(chrom.sequence, starts, ends)

Arguments
- chrom.sequence: Chromosome sequence, usually obtained from the assembly’s genome definition. This must be an object of type MaskedDNAString.
- starts: integer vector of start positions for the regions of interest.
- ends: integer vector of end positions for the regions of interest.

Value
Table of statistics for the regions in the form of a matrix with the following columns: "CpG" and "GC". The columns contain the number of CpG dinucleoties and the number of C and G bases in each region.

Author(s)
Yassen Assenov

get.files

Description
Gets the list of all files that are planned to be generated, or were already generated by the given report plot.

Usage
get.files(report.plot)

Arguments
- report.plot: Report plot of interest. This must be an object of type ReportPlot.

Value
Non-empty character vector of absolute file names.
Author(s)

Yassen Assenov

Examples

```r
## Not run:
plot.image <- createReportPlot('scatterplot', high.png = 200)
get.files(plot.image)

## End(Not run)
```

Description

Gets all region types represented in the object as character vector

Usage

```r
## S4 method for signature 'RnBDiffMeth'
get.region.types(object)
```

Arguments

- `object`: RnBDiffMeth object

Value

character vector containing region types

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Sample_Group","Treatment"))
get.region.types(dm)

## End(Not run)
```
Description

Gets the site testing method used to obtain the p-values in the differential methylation tables

Usage

```r
## S4 method for signature 'RnBDiffMeth'
get.site.test.method(object)
```

Arguments

- `object`: RnBDiffMeth object

Value

character describing the site test method

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example,pheno.cols=c("Sample_Group","Treatment"))
get.site.test.method(dm)
## End(Not run)
```

Description

Gets a differential methylation table

Usage

```r
## S4 method for signature 'RnBDiffMeth'
get.table(object, comparison, region.type, undump = TRUE, return.data.frame = FALSE)
```
getExecutables,ClusterArchitecture,character-method

Arguments

Object

Comparison

Region type

Undump

Return data frame

Value

differential methylation table. See `computeDiffMeth.bin.site` and `computeDiffMeth.bin.region` for details.

Author(s)

Fabian Mueller

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example,pheno.cols=c("Sample_Group","Treatment")
dm.promoters <- get.table(dm,get.comparisons(dm)[1],"promoters",return.data.frame=TRUE)
summary(dm.promoters)
## End(Not run)

getExecutable,ClusterArchitecture,character-method

getExecutable-methods

Description

Retrieves the executable associated with a name/identifier

Usage

## S4 method for signature 'ClusterArchitecture,character'
getExecutable(object, exec.name)

Arguments

Object

Executable

Name/identifier

Value

The executable. If the name is not associated with any executable, the names will be returned and a warning will be raised.
**getModuleNumCores,RnBClusterRun-method**

**Author(s)**
Fabian Mueller

**Description**
Retrieves the number of cores used by each module

**Usage**
```r
## S4 method for signature 'RnBClusterRun'
getModuleNumCores(object)
```

**Arguments**
- `object`: RnBClusterRun object

**Value**
A named vector containing the number of cores for each module

**Author(s)**
Fabian Mueller

---

**getSubCmdStr,ClusterArchitecture-method**

**Description**
Returns a string for the of command line corresponding to submitting a job with the given command to the cluster.

**Usage**
```r
## S4 method for signature 'ClusterArchitecture'
getSubCmdStr(object, ...)
```

**Arguments**
- `object`: ClusterArchitecture object
  - `...`: arguments passed on to `getSubCmdTokens,ClusterArchitecture-method`

**Value**
A string containing the submission command
getSubCmdTokens, ClusterArchitecture-method

Description

Returns a string for the of command line corresponding to submitting a job with the given command to the cluster.

Usage

```r
## S4 method for signature 'ClusterArchitecture'
getSubCmdTokens(object, cmd.tokens, log, 
job.name = "", res.req = character(0), depend.jobs = character(0))
```

Arguments

- `object` : `ClusterArchitecture` object
- `cmd.tokens` : a character vector specifying the executable command that should be wrapped in the cluster submission command
- `log` : file name and path of the log file that the submitted job writes to
- `job.name` : name of the submitted job
- `res.req` : character vector specifying required resources. The resource requirements should be the values of the vector, the names should specify the resource name
- `depend.jobs` : character vector containing names or ids of jobs the submitted job will depend on.

Details

For a concrete child class implementation for a sun grid architecture specification see `getSubCmdTokens, ClusterArchitectureSGE-method`

Value

A character vector containing the submission command tokens

Author(s)

Fabian Mueller
**Description**

Returns a string for the command line corresponding to submitting a job with the given command to the cluster.

**Usage**

```r
## S4 method for signature 'ClusterArchitectureSGE'
getSubCmdTokens(object, cmd.tokens, log, 
    job.name = "", res.req = character(0), depend.jobs = character(0),
    sub.binary = TRUE, quote.cmd = TRUE)
```

**Arguments**

- `object`: `ClusterArchitectureSGE` object
- `cmd.tokens`: a character vector specifying the executable command that should be wrapped in the cluster submission command
- `log`: file name and path of the log file that the submitted job writes to
- `job.name`: name of the submitted job
- `res.req`: character vector specifying required resources. The resource requirements should be the values of the vector, the names should specify the resource name
- `depend.jobs`: character vector containing names or ids of jobs the submitted job will depend on.
- `sub.binary`: treat the command as binary (see `-b` flag of `qsub` of the SGE documentation)
- `quote.cmd`: Flag indicating whether the submitted command should also be wrapped in quotes

**Details**

For a concrete child class implementation for a sun grid architecture specification see `ClusterArchitectureSGE`.

**Value**

A character vector containing the submission command tokens

**Author(s)**

Fabian Mueller

**Examples**

```r
## Not run:
arch <- new("ClusterArchitectureSGE",
    name="my_sge_architecture"
 )
getSubCmdTokens(arch,c("Rscript","my_great_script.R"),"my_logfile.log")

## End(Not run)
```
**greedycut.filter.matrix**

**Description**
Perform all iterations of the Greedycut algorithm for removing rows and columns from the given matrix.

**Usage**

```r
greedycut.filter.matrix(mm, rows2ignore = integer(), rc.ties = "row")
```

**Arguments**
- `mm`: Numeric matrix to filter.
- `rows2ignore`: integer vector containing indices of rows in `mm` to be ignored by this function.
- `rc.ties`: Flag indicating what the behaviour of the algorithm should be in case of ties between values of rows and columns. The value of this parameter must be one of "row", "column" or "any" (the last one indicating random choice).

**Value**
Table summarizing the iterations of the algorithm in the form of a `data.frame` with the following columns: Index, Type, Score, Normalized score, Rows, Columns.

**Author(s)**
Yassen Assenov

**See Also**
- `greedycut.get.submatrix` for extracting the resulting matrix after filtering

---

**greedycut.get.statistics**

**Description**
Calculates various statistics on the iterations of Greedycut.

**Usage**

```r
greedycut.get.statistics(filterinfo)
```

**Arguments**
- `filterinfo`: Information on the filtering iterations as a `data.frame` returned by `greedycut.filter.matrix`.
Value

Additional statistics on the iterations in the form of a data.frame with the following columns:
"Elements retained","Elements removed","Mismatches retained","Mismatches removed"
"False Positive Rate","Sensitivity","D". The last column signifies distance from
the diagonal in a ROC curve.

Author(s)

Yassen Assenov

greedycut.get.submatrix

Description

Filters a data matrix executing the given number of iterations of Greedycut.

Usage

greedycut.get.submatrix(mm, filter.info, it.num = nrow(filter.info) -
as.integer(1))

Arguments

mm Data matrix to be filtered.
filter.info Information on the filtering iterations as a data.frame returned by greedycut.filter.matrix.
it.num Number of iterations to execute. Defaults to all iterations.

Value

Data matrix containing subsets of the rows and columns of mm.

Author(s)

Yassen Assenov

has.covariates.ct

Description

Checks whether the given RnBSet object contains cell type contribution estimates.

Usage

has.covariates.ct(rnb.set)
has.covariates.sva

Arguments

- `rnb.set` - RnBSet object

Value

- `TRUE` if the supplied object contains the cell type covariates information and `FALSE` otherwise

Description

Returns whether Surrogate Variables have been computed and added to the `rnb.set` for a given target variable

Usage

```
has.covariates.sva(rnb.set, target)
```

Arguments

- `rnb.set` - RnBSet object
- `target` - target variable. Must be in `pheno(rnb.set)` and belong to target variables for which the SVs have already been computed and stored in the RnBSet.

Value

`logical(1)`

Author(s)

Fabian Mueller

Examples

````
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
sva.obj <- rnb.execute.sva(rnb.set.example,c("Sample_Group","Treatment"),numSVmethod="be")
sva.obj$sva.performed
sva.obj$num.components
rnb.set.mod <- set.covariates.sva(rnb.set.example, sva.obj)
has.covariates.sva(rnb.set.example,"Sample_Group")
has.covariates.sva(rnb.set.mod,"Sample_Group")
has.covariates.sva(rnb.set.mod,"Treatment")

## End(Not run)
```
**Description**

Initialize an ClusterArchitecture object

**Usage**

```r
## S4 method for signature 'ClusterArchitecture'
initialize(.Object,
    name = "ClusterArchitecture")
```

**Arguments**

- `name`: A name or identifier

**Author(s)**

Fabian Mueller

---

**initialize,ClusterArchitectureSGE-method**

**Description**

Initialize an ClusterArchitecture object for a Sun Grid Engine (SGE)

**Usage**

```r
## S4 method for signature 'ClusterArchitectureSGE'
initialize(.Object,
    name = "ClusterArchitectureSGE", ...)
```

**Arguments**

- `name`: A name or identifier
- `...`: arguments passed on to the constructor of `ClusterArchitecture` (the parent class)

**Author(s)**

Fabian Mueller
initialize,RnBClusterRun-method

**Description**

Initialize an RnBClusterRun object

**Usage**

```r
## S4 method for signature 'RnBClusterRun'
initialize(.Object, architecture)
```

**Arguments**

- `.Object` New instance of `RnBClusterRun`
- `architecture` A `ClusterArchitecture` object managing the settings for a scientific compute cluster.

**Author(s)**

Fabian Mueller

initialize,RnBDiffMeth-method

**Description**

Initialize an RnBDiffMeth object

**Usage**

```r
## S4 method for signature 'RnBDiffMeth'
initialize(.Object, 
  site.test.method = rnb.getOption("differential.site.test.method"), 
  covg.thres = rnb.getOption("filtering.coverage.threshold"), 
  disk.dump = FALSE, disk.path = NULL)
```

**Arguments**

- `.Object` New instance of `RnBDiffMeth`
- `site.test.method` method which was applied to obtain the site-level p-values.
- `covg.thres` coverage threshold. Important for certain columns of the differential methylation tables. See `computeDiffMeth.bin.site` and `computeDiffMeth.bin.region` for details.
- `disk.dump` Flag indicating whether the tables should be stored on disk rather than in the main memory.
- `disk.path` Path on the disk for DMTs. Only meaningful if `disk.dump` is TRUE.
intensities.by.color

Author(s)
Fabian Mueller

Description
Rearranges information from "M" and "U" slots of a RnBeadsRawSet object by color channel.

Usage
intensities.by.color(raw.set, address.rownames = TRUE, add.oob = TRUE, add.controls = TRUE, add.missing = TRUE)

Arguments
raw.set RnBeadRawSet object
address.rownames
  if TRUE the rows of the returned matrices are named with the with the corresponding Illumina probe addresses
add.oob if TRUE the "out-of-band" intensities are included
add.controls if TRUE the control probe intensities are included
add.missing if TRUE the rows for the probes missing in raw.set is imputed with NA values

Author(s)
Pavlo Lutsik

is.valid,RnBDiffMeth-method

Description
Validate an RnBDiffMeth object, ie. verify that all differential methylation tables are specified and accounted for

Usage
## S4 method for signature 'RnBDiffMeth'
is.valid(object, verbose = FALSE)

Arguments
object RnBDiffMeth object
verbose print more info to the logger
Value

TRUE iff all differential methylation tables are present and accounted for

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm1 <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Sample_Group"), region.types=c("genes","tiling"))
dm2 <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Sample_Group","Treatment"), region.types=c("promoters"))
dm.join1 <- join.diffMeth(dm1,dm2)
#the following joint object is invalid, because some region type - comparison combination is invalid(dm.join1)
dm3 <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Treatment"), region.types=c("genes","tiling"))
dm.join2 <- join.diffMeth(dm.join1,dm3)
#after joining the missing information, the new object is valid
is.valid(dm.join2)
## End(Not run)
```

Description

Merges two disjoint RnBDiffMeth objects into one. Disjoint here means, that no differential methylation table is specified in both objects.

Usage

```r
## S4 method for signature 'RnBDiffMeth,RnBDiffMeth'
join.diffMeth(obj1, obj2)
```

Arguments

- `obj1`: RnBDiffMeth object. Its base properties will be used to create the joint object. this is particularly imported for disk dumped objects as its path will be used and tables from the second object will be copied there
- `obj2`: RnBDiffMeth object

Value

the merged RnBDiffMeth object
Caveat: if disk dumping is enabled the resulting object tables will be stored in the initial location of the first object to be joined. I.e. deleting the first object will lead to a broken joined object and deleting the joined object will lead to an broken first object.

Author(s)
Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm1 <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Sample_Group"),
region.types=c("genes","tiling"))
dm2 <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Sample_Group","Treatment"),
region.types=c("genes","tiling"))
dm.join1 <- join.diffMeth(dm1,dm2)
#the following joint object is invalid, because some region type - comparison combination
#is.valid(dm.join1)
dm3 <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Treatment"),
region.types=c("genes","tiling"))
dm.join2 <- join.diffMeth(dm.join1,dm3)
#after joining the missing information, the new object is valid
is.valid(dm.join2)
## End(Not run)
```

Description

applies hierarchical modeling anlalogous to differential expression employed in the `limma` package and returns p-values for differential methylation

Usage

```r
limmaP(X, inds.g1, inds.g2 = -inds.g1, adjustment.table = NULL,
fun.conversion = rnb.beta2mval, paired = FALSE)
```

Arguments

- **X**: Matrix on which the test is performed for every row
- **inds.g1**: column indices of group 1 members
- **inds.g2**: column indices of group 2 members
- **adjustment.table**: a data.frame containing variables to adjust for in the testing
- **fun.conversion**: conversion function to transform the beta values into M values. By default, it is the logit function with adjustment for infinity values. See `rnb.beta2mval` for details.
- **paired**: should a paired analysis model be used. If so, the first index in `inds.g1` must correspond to the first index in `inds.g2` and so on.
Value

vector of p-values resulting from limma’s differential analysis

Note

Requires `limma` package

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
meth.mat <- meth(rnb.set.example)
sample.groups <- rnb.sample.groups(rnb.set.example)[[1]]
p.vals <- limmaP(meth.mat,sample.groups[[1]],sample.groups[[2]])
## End(Not run)
```

load.region.subsegment.annotation

For the region annotation of a given `RnBSet` object. Subdivide each region into subsegments by hierarchical clustering on the site distances in a particular region and then splitting the region into subregions consisting of these site clusters. The number of clusters is determined in such way that the mean number of sites per cluster is given by the `ns` parameter.

Usage

```r
load.region.subsegment.annotation(rnb.set, annotation.dir)
```

Arguments

- `rnb.set`: The `RnBSet` object with subsegments specified in the regions
- `annotation.dir`: a directory to load the annotation from. (binary `RData` format.)

Value

invisible `TRUE`

Author(s)

Fabian Mueller
**Description**
load a saved RnBDiffMeth object from disk

**Usage**
load.rnb.diffmeth(path)

**Arguments**
- *path* path of the saved object (a directory containing a corresponding rnbDiffMeth.RData file and possibly rnbDiffMeth_tables files)

**Value**
the loaded RnBDiffMeth object

**Author(s)**
Fabian Mueller

---

**Description**
Loading of the RnBSet objects with large matrices of type ff.

**Usage**
load.rnb.set(path, temp.dir = tempdir())

**Arguments**
- *path* full path of the file or directory. If archive is FALSE) without an extension.
- *temp.dir* character singleton which specifies temporary directory, used while loading

**Value**
Loaded object

**Author(s)**
Pavlo Lutsik
Description

Reads a command-line argument supplied to a script.

Usage

```r
logger.argument(arg.names, full.name, arg.type = "character",
accepted.values = NULL, default = NULL, arg.list = commandArgs())
```

Arguments

- **arg.names** character vector of acceptable argument names. This function scans the provided arguments and performs a case insensitive match.
- **full.name** One-element character vector giving the argument’s full name or description. This is used in a log message in case of an error.
- **arg.type** Variable type of the argument. Must be one of "character", "logical", "integer", "double", "numeric" or "real". The last three types are all synonyms.
- **accepted.values** Vector of accepted values for the argument. This must be of the type given in arg.type. Set this to NULL if there are no restrictions on the argument values.
- **default** Default value for the argument in case it is not specified. Setting this to NULL makes the argument required, that is, an error is generated if the argument is not specified. Set this to NA if it is not a required argument and it shouldn’t default to a specific value. Otherwise, if accepted.values is provided, this must be one of its elements.
- **arg.list** Vector of arguments provided at the execution of the script. The arguments should be provided as name=value pairs.

Details

This is convenience function for reading parameters supplied to the script in the form name = value. It expects that logging is enabled (see `rnb.options`). The function fails if this condition is not met.

Value

Argument’s value, or NULL if such is not provided.

Author(s)

Yassen Assenov
logger.getfiles

Examples

## Not run:

n.iterations <- logger.argument("iterations", "number of iterations", "integer",
  accepted.values = 1:100, default = 1L)
logger.close()

## End(Not run)

logger.getfiles

logger.getfiles

Description

Gets the files currently used by the logger.

Usage

logger.getfiles()

Value

Vector storing the full names of the files that are being used by the logger. This vector contains
NA as an element if the logger is (also) using the console for its output. If logging functionality is
disabled (see rnb.options) or the logger is not initialized, this function returns NULL.

Author(s)

Yassen Assenov

See Also

logger.isinitialized to check if logging is activated; logger.start for initializing a
logger or starting a section

Examples

## Not run:

if (NA %in% logger.getfiles())
  cat("Console logger is enabled\n")

## End(Not run)
**logger.isinitialized**

**Description**
Checks if the logger is initialized.

**Usage**
```r
logger.isinitialized()
```

**Value**
TRUE if the logger was initialized and is in use; FALSE otherwise.

**Author(s)**
Yassen Assenov

**See Also**

*logger.start* for initializing a logger or starting a section

**Examples**
```r
## Not run:
if (!logger.isinitialized())
  logger.start(fname = NA)
## End(Not run)
```

---

**logger.machine.name**

**Description**
log the machine name the analysis is run on

**Usage**
```r
logger.machine.name()
```

**Author(s)**
Fabian Mueller
logger.start

Log File Management

Description
Functions for logger management.

Usage

```r
logger.start(txt = character(0), fname = NULL)
logger.completed()
logger.close()
```

Arguments

- `txt` Description to add to the log file. The words `STARTED` and `COMPLETED` are prepended to the message upon initialization and completion of the section, respectively.
- `fname` Name of the log file and/or console. Note that at most one file name can be specified. The function `logger.start` normalizes the given name, that is, it converts it to an absolute name. If this parameter is `NA`, logger messages are printed to the console. If it is a two-element vector containing one file name and `NA`, the logger is (re)initialized to print messages both to the given file name and the console. A value of `NULL` (default) indicates the logger should continue using the previously specified file.

Details

- `logger.start` initializes the logger and/or starts a new section. `logger.completed` completes the last (innermost) open section in the log. `logger.close` deinitializes the logger. Note that after reinitialization or deinitialization, the information about the current output file, as well as any open sections, is deleted.

Author(s)

Yassen Assenov

See Also

- `logger.isinitialized`

Examples

```r
## Not run:
if (!logger.isinitialized())
  logger.start(fname = NA)
logger.start("Tests for Significance")
logger.completed()
logger.close()

## End(Not run)
```
logger.status  Writing text messages to the log file.

Description

Appends a single-line status message to the log text file. The message is prepended by its type, which is one of STATUS, INFO, WARNING or ERROR.

Usage

logger.status(txt)
logger.info(txt)
logger.warning(txt)
logger.error(txt, terminate = rnb.getOption("logging.exit.on.error"))

Arguments

- **txt**: Text to add to the log file. This must be a character vector; its elements are concatenated using a single space (" ") as a separator.
- **terminate**: Flag indicating if the execution is to be terminated after this error message is added to the log.

Author(s)

Yassen Assenov

See Also

logger.isinitialized to check if logging is activated; logger.start for initializing a logger or starting a section

Examples

```r
## Not run:
if (!logger.isinitialized())
  logger.start(fname = NA)
logger.status(c("Reached step", 2))
logger.info(c("Provided email:", rnb.getOption("email")))
## End(Not run)
```
Description

Validates the specified file or directory exists. Prints an error or a warning message to the log if it does not exist, it is not of the accepted type or is not accessible.

Usage

logger.validate.file(file, is.file = TRUE, terminate = TRUE)

Arguments

file Name of file or directory to validate.

is.file Flag indicating if the given name must denote an existing file. If this is FALSE, the given name must denote a directory. Set this to NA if both types are an acceptable scenario.

terminate Flag indicating if the execution is to be terminated in case the validation fails. This parameter determines if an error message (terminate is TRUE) or a warning message (terminate is FALSE) is to be sent to the log when the specified file or directory does not exist, is not of the accepted type or is not accessible.

Value

Whether the validation succeeded or not, invisibly. Note that when terminate is TRUE and the validation fails, the R session is closed and thus no value is returned.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
if (!logger.isinitialized())
  logger.start(fname = NA)
# Validate the current working directory exists
logger.validate.file(getwd(), FALSE)
## End(Not run)
```
Description

Extract raw methylated probe intensity from an object of RnBeadRawSet class.

Usage

## S4 method for signature 'RnBeadRawSet'
M(object, row.names = FALSE)

Arguments

object
  Dataset of interest.

row.names
  Flag indicating whether the resulting matrix will be assigned row names

Value

matrix of the methylated probe intensities

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
M.intensity<-M(rnb.set.example)
head(M.intensity)

## End(Not run)

mergeSamples

Description

Take an RnBSet object and merge methylation and phenotype information given a grouping column in the pheno table coverage is combined by taking the sum of coverages pheno is combined by concatenating entries from all samples.

Usage

## S4 method for signature 'RnBSet'
mergeSamples(object, grp.col)
meth,RnBSet-method

Arguments

- **object**: input RnBSet object
- **grp.col**: a column name (string) of pheno(rnb.set) that contains unique identifiers for sample groups/replicates to be combined

Details

Combines phenotype information, coverage information and methylation information. Methylation is combined by taking the average. Detection p-values are combined using Fisher’s method. For methylation arrays, bead counts are currently not taken into account. Objects of class RnBeadRawSet are automatically converted to RnBeadSet.

Value

- the modified RnBSet object

Note

- Requires the packages *foreach* and *doParallel*.

Author(s)

- Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.set.example
rnb.set.merged <- mergeSamples(rnb.set.example,"Cell_Line")
rnb.set.merged
pheno(rnb.set.merged)
## End(Not run)
```

meth,RnBSet-method *meth-methods*

Description

- Extracts DNA methylation information (beta values) for a specified set of genomic features.

Usage

```r
## S4 method for signature 'RnBSet'
meth(object, type = "sites", row.names = FALSE)
```
mval,RnBSet-method

Description

Extracts DNA methylation information (M values) for a specified set of genomic features.

Usage

```r
## S4 method for signature 'RnBSet'
mval(object, type = "sites", row.names = FALSE, epsilon = 0)
```

Arguments

- **object**: dataset of interest.
- **type**: character singleton. If this is set to "sites" (default), DNA methylation information for each available site is returned. Otherwise, this should be one of region types for for which summarized DNA methylation information is computed in the given dataset.
- **row.names**: flag indicating if row names are to be generated in the result.
- **epsilon**: Threshold of beta values to use when adjusting for potential M values close to +infinity or -infinity. See `rnb.beta2mval` for more details.

Value

_matrix with methylation beta values._

See Also

- mval for calculating M values

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
## per-site beta-value matrix
mm<-meth(rnb.set.example, row.names=TRUE)
head(mm)
## beta-values for each covered gene
gmm<-meth(rnb.set.example, type="gene", row.names=TRUE)
head(gmm)
## End(Not run)
```
Value

\text{matrix} with methylation M values.

See Also

\text{meth} for extracting methylation beta values

Examples

\texttt{## Not run:}
\texttt{library(RnBeads.hg19)}
\texttt{data(small.example.object)}
\texttt{## per-site M-value matrix}
\texttt{mm<-mval(rnb.set.example, row.names=TRUE)}
\texttt{head(mm)}
\texttt{## M-values for each covered gene}
\texttt{gmm<-mval(rnb.set.example, type="gene", row.names=TRUE)}
\texttt{head(gmm)}

\texttt{## End(Not run)}

Description

Performs cleanup and/or other finishing activities and closes the specified device, connection, or document.

Usage

\texttt{## S4 method for signature 'Report'}
\texttt{off(.Object)}

\texttt{## S4 method for signature 'ReportPlot'}
\texttt{off(.Object)}

\texttt{## S4 method for signature 'ReportGgPlot'}
\texttt{off(.Object, handle.errors = FALSE)}

Arguments

\texttt{.Object} Object to be closed.
\texttt{handle.errors} Flag indicating if the method should attempt to catch and process errors (e.g. I/O errors) internally. Setting this to \texttt{TRUE} does not guarantee that the method never stops with an error.

Value

The closed object, invisibly.
**parallel.disable**

Description

Disables parallel processing.

Usage

```r
## S3 method for class 'disable'
parallel()
```

Author(s)

Fabian Mueller

Examples

```r
## Not run:
parallel.getNumWorkers()
parallel.setup(2)
parallel.getNumWorkers()
parallel.disable()
parallel.getNumWorkers()

## End(Not run)
```

**parallel.getNumWorkers**

Description

Return the number of workers used for parallel processing.

Usage

```r
## S3 method for class 'getNumWorkers'
parallel()
```

Author(s)

Fabian Mueller
**parallelisEnabled**

**Examples**

```r
## Not run:
parallel.getNumWorkers()
parallel.setup(2)
parallel.getNumWorkers()
parallel.disable()
parallel.getNumWorkers()

## End(Not run)
```

---

**Description**

Checks if whether parallel processing is enabled.

**Usage**

```r
## S3 method for class 'isEnabled'
parallel()
```

**Value**

TRUE if multicore processing is enabled, FALSE otherwise.

**Author(s)**

Fabian Mueller

**Examples**

```r
## Not run:
parallel.isEnabled()
parallel.setup(2)
parallel.isEnabled()
parallel.disable()
parallel.isEnabled()

## End(Not run)
```
Description

Sets up parallel processing. Requires the \texttt{foreach} and \texttt{doParallel} packages.

Usage

```r
## S3 method for class 'setup'
parallel(...)
```

Arguments

... Parameters for \texttt{registerDoParallel} from the \texttt{doParallel} package. This allows, for instance, for specifying the number of workers.

Value

\texttt{TRUE} (invisible) to indicate that parallelization is set up.

Note

Requires the packages \texttt{foreach} and \texttt{doParallel}.

Author(s)

Fabian Mueller

Examples

```r
## Not run:
parallel.setup(2)
## End(Not run)
```

Description

performs Geno Ontology (GO) enrichment analysis for a given differential methylation table.

Usage

```r
performEnrichment.diffMeth(rnbSet, diffmeth, ontologies = c("BP", "MF"), 
rank.cuts.region = c(100, 500, 1000), add.auto.rank.cut = TRUE, 
rerank = TRUE, verbose = TRUE, ...)
```
performGOenrichment.diffMeth.entrez

Arguments

rnbSet RnBSet object for which differential methylation was computed
diffmeth RnBDiffMeth object. See RnBDiffMeth-class for details.
ontologies GO ontologies to use for enrichment analysis
rank.cuts.region Cutoffs for combined ranking that are used to determine differentially methylated regions
add.auto.rank.cut flag indicating whether an automatically computed cut-off should also be considered.
rerank For determining differential methylation: should the ranks be ranked again or should the absolute ranks be used.
verbose Enable for detailed status report
...

Value

a DiffMeth.enrich object (S3) containing the following attributes

region Enrichment information for differential methylation on the region level. See GOHyperGresult from the GOstats package

Author(s)

Fabian Mueller

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)

res <- performEnrichment.diffMeth(rnb.set.example, pheno.cols=c("Sample_Group","Treatment"),

## End(Not run)

Description

performs Gene Ontology (GO) enrichment analysis for a list of Entrez identifiers

Usage

performGOenrichment.diffMeth.entrez(gids, uids, ontology, assembly = "hg19",
...
Arguments

gids   gene ids to test (entrez IDs)
uids   ids to test against (universe)
ontology which ontology should be used (see GOHyperGParams from the GOstats package for details)
assembly Genome to be used. One of the following: hg19, mm9, mm10 or rn5
...   arguments passed on to the parameters of GOHyperGParams from the GOstats package

Value

a GOHyperGresult object (see the GOstats package for further details)

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example,pheno.cols=c("Sample_Group","Treatment"))
dmt <- get.table(dm,get.comparisons(dm)[1],"promoters")
annot <- annotation(rnb.set.example,"promoters")
all.promoters <- annot$entrezID
hyper.promoters <- annot$entrezID[dmt[,"mean.mean.diff"]>0]
result <- performGOenrichment.diffMeth.entrez(hyper.promoters,all.promoters,"BP",assembly="hg19")
## End(Not run)
```
Value

Sample annotation information available for the dataset in the form of a \texttt{data.frame}.

Examples

\begin{verbatim}
## Not run:
library(RnBeads.hg19)
data(small.example.object)
pheno(rnb.set.example)

## End(Not run)
\end{verbatim}

Description

Extracts HumanMethylation quality control information

Usage

\begin{verbatim}
## S4 method for signature 'RnBeadSet'
qc(object)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{object} : Dataset of interest.
\end{itemize}

Value

Quality control information available for the dataset in the form of a \texttt{list} with two elements: \texttt{Cy3} and \texttt{Cy5}.

Examples

\begin{verbatim}
## Not run:
library(RnBeads.hg19)
data(small.example.object)
qcinf<-dpval(rnb.set.example, row.names=TRUE)
head(qcinf$Cy3)
head(qcinf$Cy5)

## End(Not run)
\end{verbatim}
Description

Reads a reduced-representation/whole-genome bisulfite sequencing data set from a set of BED files

Usage

```
read.bed.files(base.dir = NULL, file.names = NULL, sample.sheet = NULL,
                file.names.col = 0, assembly = rnb.getOption("assembly"),
                region.types = rnb.region.types.for.analysis(rnb.getOption("assembly")),
                coord.shift.plus = 1L, skip.lines = 1,
                sep.samples = rnb.getOption("import.table.separator"),
                merge.bed.files = TRUE, useff = rnb.getOption("disk.dump.big.matrices"),
                verbose = TRUE, ...)
```

Arguments

- `base.dir` Directory with 6+2 formatted BED files containing processed methylation data
- `file.names` Optional non-empty character vector listing the names of the files that should be loaded relative to `base.dir`. If supplied, this vector must not contain `NA` among its elements.
- `sample.sheet` Optional file name containing a table of sample annotation data, or the table itself in the form of a `data.frame` or `matrix`. Only (and all) samples defined in this table will be loaded. The table is expected to contain a column named "barcode" that lists the samples’ Sentrix barcodes. If such a column is not present, this function searches for columns "Sentrix_ID" and "Sentrix_Position" (or similar) that build a barcode.
- `file.names.col` Column of the sample sheet which contains the file names (integer singleton). If `NA` an attempt will be made to find a suiting column automatically.
- `assembly` Genome assembly. Defaults to human ("hg19")
- `region.types` character vector storing the types of regions for which the methylation information is to be summarized. The function `rnb.region.types` provides the list of all supported regions. Setting this to `NULL` or an empty vector restricts the dataset to site methylation only.
- `coord.shift.plus` The frame shift between the the CpG annotation (1-based) and the coordinates in the loaded BEDs. If BEDs have 0-based coordinates, `coord.shift.plus=1` (default).
- `skip.lines` The number of top lines to skip while reading the BED files
- `sep.samples` character singleton used as field separator in the sample sheet file. Default value is taken by the call to `rnb.getOption("import.table.separator")`
- `merge.bed.files` In case multiple BED files are specified for each sample, the flag indicates whether the methylation calls should be merged after reading
- `useff` If `TRUE`, functionality provided by the `ff` package will be used to read the data efficiently.
read.data.dir

<table>
<thead>
<tr>
<th>verbose</th>
<th>Flag indicating if the messages to the logger should be sent. Note that the logger must be initialized prior to calling this function. Logging is useful for keeping a record of the downloaded and processed samples. Also, informative messages are stored in case of an error.</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td>Further arguments which are passed to the internal function read.bissnp.bed and to read.table</td>
</tr>
</tbody>
</table>

Details

Each loaded BED file should follow the 6+2 convention: six standard BED columns (chromosome, start, end, feature.name, feature value, strand) plus two additional columns – mean methylation level of a methylation site and the number of reads covering it.

Author(s)

Pavlo Lutsik

Description

Reads in a directory with Illumina Infinium HumanMethylation450 data. The files should be stored as data.

Usage

read.data.dir(dir, pheno, betas, p.values, bead.counts, sep = rnb.getOption("import.table.separator"), verbose = TRUE)

Arguments

dir | directory containing the table files
pheno | a file containing data sample annotations and phenotypic information
betas | a file containing the beta values. If not supplied, the routine will look in dir for a file containing "beta" token in the filename
p.values | a file containing the detection p values. If not supplied, the routine will look in dir for a file containing "pval" token in the filename
bead.counts | a file containing the bead counts (optional). If not supplied, the routine will look in dir for a file containing "bead" token in the filename
sep | character used as field separator in the tables files. Default value is taken by the call to rnb.getOption("import.table.separator")
verbose | Flag indicating if the messages to the logger should be sent. Note that the logger must be initialized prior to calling this function. Logging is useful for keeping a record of the downloaded and processed samples. Also, informative messages are stored in case of an error.

Details

Colnames in all files should match. They will be returned as the samples element of the list.
Value

Object of type RnBeadSet.

Author(s)

Pavlo Lutsik

Description

Imports Infinium 450K data series from the Gene Expression Omnibus.

Usage

read.geo(accession = NULL, filename = NULL, verbose = logger.isinitialized(), destdir = tempdir(), parse.characteristics_ch1 = TRUE)

Arguments

accession  Character string representing the GEO series for download and parsing. It must start with "GSE".
filename  File name of a previously downloaded GEO series matrix file or its gzipped representation (in which case the filename must end in ".gz"). Other file formats, such as SOFT files, are not supported. Exactly one of accession or filename must be specified.
verbose  Flag indicating if messages should be created informing about the progress. If the logger is initialized prior to calling this function, the informative messages are sent to the logger. Warnings and errors are not affected by this parameters, the function always outputs them.
destdir  The destination directory for any downloads. Defaults to the (architecture-dependent) temporary directory. Keep in mind that GEO series can be demanding in terms of storage space.
parse.characteristics_ch1  Flag indicating if additional sample characteristics (if such exist) are to be parsed from the downloaded series matrix file(s).

Value

RnBeadSet object with phenotypic and beta value information; NULL if the given series contain no Infinium450K samples.

Author(s)

Yassen Assenov

See Also

getGEO in package GEOquery
Description

Parses the sample information in all of the characteristics_ch1 columns from a phenoData data frame as obtained from getGEO.

Usage

read.geo.parse.characteristics_ch1(phenoData)

Arguments

phenoData Parsed phenotypic data frame object as output by getGEO.

Value

Phenotypic data frame with parsed sample information instead of characteristics_ch1.

Author(s)

Fabian Mueller

See Also

getGEO in package GEOquery

Description

Reads in a Genome Studio report, exported as a single file.

Usage

read.GS.report(gsReportFile, pd = NULL, sep = rnb.getOption("import.table.separator"), keep.methylumi = FALSE, verbose = TRUE)
Arguments

- **gsReportFile**: location of the GS report file
- **pd**: alternative sample annotation, if the `gsReportFile` is missing the sample section as `data.frame` of character singleton with the file name
- **sep**: character used as field separator in the sample sheet file and in the GS report file (should be identical). Default value is taken by the call to `rnb.getOption("import.table.separator")`
- **keep.methylumi**: a flag indicating whether the a `MethyLumiSet` object should be returned instead of a `RnBeadRawSet`
- **verbose**: Flag indicating if the messages to the logger should be sent. Note that the logger must be initialized prior to calling this function. Logging is useful for keeping a record of the downloaded and processed samples. Also, informative messages are stored in case of an error.

Value

`MethyLumiSet` object with the data from the report

Description

Reads a directory of `.idat` files and initializes an object of type `MethyLumiSet`.

Usage

```r
read.idat.files(base.dir, barcodes = NULL, sample.sheet = NULL, sep.samples = rnb.getOption("import.table.separator"), useff = FALSE, verbose = TRUE)
```

Arguments

- **base.dir**: Directory that contains the `.idat` files to be read; or a character vector of such directories.
- **barcodes**: Optional non-empty character vector listing the barcodes of the samples that should be loaded. If supplied, this vector must not contain `NA` among its elements.
- **sample.sheet**: Optional file name containing a table of sample annotation data, or the table itself in the form of a `data.frame` or matrix. Only (and all) samples defined in this table will be loaded. The table is expected to contain a column named "barcode" that lists the samples’ Sentrix barcodes. If such a column is not present, this function searches for columns "Sentrix_ID" and "Sentrix_Position" (or similar) that build a barcode.
- **sep.samples**: character string used as field separator in the sample sheet file. Default value is taken by the call to `rnb.getOption("import.table.separator")`
- **useff**: If `TRUE` `ff` package is used to store large matrices on the hard disk
- **verbose**: Flag specifying whether the messages to the logger should be sent. Note that the logger must be initialized prior to calling this function. Logging is useful for keeping a record of the downloaded and processed samples. Also, informative messages are stored in case of an error.
Details

If neither barcodes, nor sample.sheet are specified, the function attempts to locate a file in base.dir containing sample annotation information. It fails if such a file cannot be (unambiguously) identified. If both barcodes and sample.sheet are supplied, only sample.sheet is used in loading methylation data. The value of barcodes is tested for validity but it is not used as a filter.

Value

Loaded dataset of HumanMethylation450K samples, encapsulated in an object of type MethyLumiSet.

Author(s)

Pavlo Lutsik

See Also

methylumIDAT in package methylumi

Description

Reads a directory of .idat files and initializes an object of type MethyLumiSet.

Usage

read.idat.files2(base.dir, barcodes = NULL, sample.sheet = NULL, sep.samples = rnb.getOption("import.table.separator"), load.chunk = NULL, keep.methylumi = FALSE, verbose = TRUE)

Arguments

base.dir Directory that contains the .idat files to be read; or a character vector of such directories.

barcodes Optional non-empty character vector listing the barcodes of the samples that should be loaded. If supplied, this vector must not contain NA among its elements.

sample.sheet Optional file name containing a table of sample annotation data, or the table itself in the form of a data.frame or matrix. Only (and all) samples defined in this table will be loaded. The table is expected to contain a column named "barcode" that lists the samples’ Sentrix barcodes. If such a column is not present, this function searches for columns "Sentrix_ID" and "Sentrix_Position" (or similar) that build a barcode.

sep.samples character used as field separator in the sample sheet file. Default value is taken by the call to rnb.getOption("import.table.separator")

load.chunk integer of size one, giving the number of IDAT files which should be loaded in one loading cycle or NULL, in which case an attempt will be made to load all files in one go. Should be assigned in case the number of IDATs is more than one thousand.
**keep.methylumi**

A flag indicating whether the `MethyLumiSet` object should be returned instead of a `RnBeadRawSet`.

**verbose**

Flag indicating if the messages to the logger should be sent. Note that the logger must be initialized prior to calling this function. Logging is useful for keeping a record of the downloaded and processed samples. Also, informative messages are stored in case of an error.

**Details**

If neither `barcodes`, nor `sample.sheet` are specified, the function attempts to locate a file in `base.dir` containing sample annotation information. It fails if such a file cannot be (unambiguously) identified. If both `barcodes` and `sample.sheet` are supplied, only `sample.sheet` is used in loading methylation data. The value of `barcodes` is tested for validity but it is not used as a filter.

**Value**

Loaded dataset of HumanMethylation450K samples, encapsulated in an object of type `MethyLumiSet`.

**Author(s)**

Pavlo Lutsik

---

**Description**

Reads Illumina Infinium sample annotation.

**Usage**

```
read.sample.annotation(fname, sep = rnb.getOption("import.table.separator"))
```

**Arguments**

- `fname`
  
  Name of text file that contains a sample annotation table with a header. This method handles a variety of file formats, including comma-separated values file exported from Genome Studio.

- `sep`
  
  One-element character used as field separator in the tables file.

**Value**

Sample annotation table in the form of a `data.frame`, in which every row corresponds to a sample, and every column - to a trait.
The function `refFreeEWASP` applies the reference-free cell-type heterogeneity adjustment model from [1] and returns corrected p-values. The function can be used for paired or unpaired analysis. It requires the package `RefFreeEWAS`.

**Description**

Applies the reference-free cell-type heterogeneity adjustment model from [1] and returns corrected p-values.

**Usage**

```r
refFreeEWASP(X, inds.g1, inds.g2 = -inds.g1, adjustment.table = NULL, paired = FALSE, nboot = 100, ignore.na = TRUE, rescale.residual = TRUE)
```

**Arguments**

- `X`: Matrix on which the test is performed for every row
- `inds.g1`: Column indices of group 1 members
- `inds.g2`: Column indices of group 2 members
- `adjustment.table`: A data.frame containing variables to adjust for in the testing
- `paired`: Should a paired analysis model be used. If so, the first index in `inds.g1` must correspond to the first index in `inds.g2` and so on.
- `nboot`: The number of bootstrapping resamples
- `ignore.na`: In this case all NA containing rows are removed
- `rescale.residual`: Rescale the residual matrix as z-scores

**Value**

A vector of p-values for the "adjusted" regression coefficients from the Reference-free EWAS model.

**Note**

Requires the package `RefFreeEWAS`.

**Examples**

```r
## Not run:
TODO add system annotation example
annotation.file<-system.file("")
sa<-read.sample.annotation(annotation.file)
sa
## End(Not run)
```
Author(s)

Pavlo Lutsik

References

regionMapping,RnBSet-method

Description

get the mapping of regions in the RnBSet object to methylation site indices in the RnBSet object

Usage

## S4 method for signature 'RnBSet'
regionMapping(object, region.type)

Arguments

- **object**: Dataset as an object of type inheriting RnBSet.
- **region.type**: region type. see rnb.region.types for possible values

Value

A list containing for each region the indices (as integers) of sites that belong to that region

Author(s)

Fabian Mueller

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
promoter.probe.list <- regionMapping(rnb.set.example,"promoters")
#get the number of CpGs per promoter in the dataset:
sapply(promoter.probe.list,length)

## End(Not run)
Description

Methylation regions, information for which is present in the RnBSet object.

Usage

## S4 method for signature 'RnBSet'
regions(object, type = NULL)

Arguments

- object: Dataset of interest.
- type: Region type(s) of interest as a character vector. If this is set to NULL, all region types summarized in the object are returned.

Value

Methylation site and region assignment. If `type` is singleton, a matrix is returned. The first column corresponds to the methylation context index. The second column is the index of the chromosome in the genome, and the third is the index of the region in the GRanges object of the region type annotation. When `length(type)>1`, a list of such matrices is returned for each element of `type`. If `type` is NULL, matrices for all summarized region types are returned.

Note

Methylation context index is an integer number denoting the sequence context of the cytosine of interest. Index 1 corresponds to CpG, the only supported index in bisulfite sequencing datasets.

Author(s)

Pavlo Lutsik

See Also

- summarized.regions for all summarized region types in a dataset; rnb.get.chromosomes listing all supported chromosomes for a given genome assembly

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
head(regions(rnb.set.example))

## End(Not run)
```
reload,RnBDiffMeth-method

Description

reload disk dumped tables. Useful if the table files are manually copied or if the object is loaded again.

Usage

```r
## S4 method for signature 'RnBDiffMeth'
reload(object, save.file, disk.path = tempfile(pattern = "diffmeth_", tmpdir = getOption("fftempdir")))
```

Arguments

- `object` \texttt{RnBDiffMeth} object
- `save.file` location of the ff data saved to disk (i.e. save in save.RData and save.ffData)
- `disk.path` path on the disk for DMTs. can be new or be the same as in the original object

Value

the updated RnBDiffMeth object

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
#compute differential methylation
dm <- rnb.execute.computeDiffMeth(rnb.set.example,pheno.cols=c("Sample_Group","Treatment"),disk.dump=TRUE,disk.dump.dir=tempfile(pattern="working"))
#get temporary file names
fn.save.tabs <- tempfile(pattern="saveTables")
fn.save.obj <- tempfile(pattern="saveObject")
#save the object and the tables to disk
save(dm,file=fn.save.obj)
save.tables(dm,fn.save.tabs)
#delete the object from the workspace
destroy(dm)
rm(dm)
#reload the object and tables
load(fn.save.obj)
dm.new <- reload(dm,fn.save.tabs)

## End(Not run)
```
Description
Removes the specified samples from the dataset.

Usage
## S4 method for signature 'RnBSet'
remove.samples(object, samplelist)

## S4 method for signature 'RnBeadRawSet'
remove.samples(object, samplelist)

## S4 method for signature 'RnBeadSet'
remove.samples(object, samplelist)

Arguments
- **object**: Dataset of interest.
- **samplelist**: List of samples to be removed in the form of a logical, integer or character vector. If this parameter is logical, it is not recycled; its length must be equal to the number of samples in object. If it is integer or character, it must list only samples that exist in the dataset. Specifying sample indices larger than the number of samples, or non-existent sample identifiers results in an error.

Value
The modified dataset.

See Also
- remove.sites for removing sites or probes from a methylation dataset

Examples
## Not run:
library(RnBeads.hg19)
data(small.example.object)
samples(rnb.set.example)
## remove 3 random samples
s2r<-sample.int(length(samples(rnb.set.example)), 3)
rnb.set.f<-remove.samples(rnb.set.example, s2r)
samples(rnb.set.f)

## End(Not run)
Description

Removes the specified probes from the dataset.

Usage

```r
## S4 method for signature 'RnBSet'
remove.sites(object, probelist, verbose = FALSE)

## S4 method for signature 'RnBeadRawSet'
remove.sites(object, probelist, verbose = TRUE)

## S4 method for signature 'RnBeadSet'
remove.sites(object, probelist, verbose = TRUE)
```

Arguments

- `object`:
  Dataset of interest.

- `probelist`:
  List of probes to be removed in the form of a logical, integer or character vector. If this parameter is logical, it is not recycled; its length must be equal to the number of probes in `object`. If it is integer or character, it must list only probes that exist in the dataset. Specifying probe indices larger than the number of probes, or non-existent probe identifiers results in an error.

- `verbose`:
  if TRUE additional diagnostic output is generated

Value

The modified dataset.

See Also

remove.samples for removing samples from a methylation dataset

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
print(rnb.set.example)
## remove 100 random sites
s2r<-sample.int(nrow(sites(rnb.set.example)), 100)
rnb.set.f<-remove.sites(rnb.set.example, s2r)
print(rnb.set.f)
```

## End(Not run)
Report-class

Description

Handler of a generated HTML report. Reports are initialized using the function `createReport`.

Slots

- `fname` Name of the file that contains the HTML report.
- `dir.conf` Directory that contains configuration files; usually shared between reports.
- `dir.data` Directory that contains the generated external lists and tables.
- `dir.pfigs` Directory that contains the generated figure image files.
- `dir.pdfs` Directory that contains the generated figure PDF files.
- `dir.high` Directory that contains the generated high-resolution image file.
- `sections` Number of sections and subsections currently added to the report.
- `opensections` Indices of currently active section and subsections.
- `figures` Number of figures currently added to the report.
- `tables` Number of selectable tables added to the report.
- `references` List of references to be added at the end of the report.

Methods and Functions

- `rnb.get.directory` Gets the location of a given report-specific directory.
- `rnb.add.section` Generates HTML code for a new section in the report.
- `rnb.add.paragraph` Generates HTML code for a new paragraph in the report.
- `rnb.add.list` Generates HTML code for a list in the report.
- `rnb.add.table` Generates HTML code for a table in the report.
- `rnb.add.tables` Generates HTML code for a listing of tables in the report.
- `rnb.add.figure` Generates HTML code for a figure in the report.
- `rnb.add.reference` Adds a reference item to the report.
- `off` Completes the HTML report by adding a reference section (if needed), a footer notice and closing the `<body>` and `<html>` tags.

Author(s)

Yassen Assenov
ReportGgPlot-class ReportGgPlot Class

Description

Information about the files created to store one generated plot in a report. Report plots are initialized using the function `createReportGgPlot`. It inherits from the `ReportPlot` class and handling is analogous, except that it contains an additional slot to store a ggplot object.

Slots

- `ggp` ggplot object to be printed

Notes

No device is being opened until `off(reportGgPlot)` is called.

Author(s)

Fabian Mueller

ReportPlot-class ReportPlot Class

Description

Information about the files created to store one generated plot in a report. Report plots are initialized using the function `createReportPlot`.

Slots

- `fname` Relative file name. It does not include path or extension.
- `width` Width of the image in inches.
- `height` Height of the image in inches.
- `create.pdf` Flag indicating if a PDF image is created.
- `low.png` Resolution, in dots per inch, used for the figure image.
- `high.png` Resolution, in dots per inch, used for the high-resolution image.
- `dir.pdf` Directory that contains the generated PDF file.
- `dir.png.low` Directory that contains the generated figure image file.
- `dir.png.high` Directory that contains the generated high-resolution image file.

Methods and Functions

- `get.files` Gets the list of all files that are planned to be generated, or were already generated by the report plot.
- `off` Copies the figure to a PNG file (if needed) and closes the device associated with the report plot.
**Description**

Generates HTML code for a figure in the specified report. A figure is a collection of images (plots), of which only one is visible at any given moment.

**Usage**

```r
rnb.add.figure(report, description, report.plots, setting.names = list(),
               selected.image = as.integer(1))
```

**Arguments**

- `report` Report to write the text to.
- `description` Human-readable description of the figure. This must be a non-empty character vector. The elements of this vector are concatenated without a separator to form the full description.
- `report.plots` Object of type `ReportPlot`, or a list of such objects.
- `setting.names` List of plot file element descriptors. Every variable elements in the plot file names must be included in this list. Set this to empty list if no variable elements are present, that is, if the figure should present a single report plot.
- `selected.image` Index of plot to be initially selected in the figure.

**Value**

The modified report.

**Author(s)**

Yassen Assenov

**See Also**

- `rnb.add.tables` for adding a listing of tables; `Report` for other functions adding contents to an HTML report.
rnb.add.list

Description
Generates HTML code for a list in the specified report.

Usage
rnb.add.list(report, txt, type = "u")

Arguments
- **report**: Report to write the text to.
- **txt**: Non-empty list of items to be written. An attribute named `type`, if it exists, specifies the type of the list. See the Details section for more information. Every item must be either a nested `list`, denoting a sublist, or a `character vector` (or array), storing the text to be written. Any other objects are coerced to a character type. Elements are concatenated without a separator to form the text for a list item.
- **type**: List type to be used for the list and/or its sublists in case the attribute `type` is not specified.

Details
There are two ways to specify a list type: (1) setting a value for the attribute `type` of the list, or (2) using the function’s parameter `type`. The value of the function’s parameter is used only for lists and sublists that do not contain an attribute named `type`. The following types are supported:

- "o": Ordered list using arabic numbers - 1, 2, 3, etc.
- "u": Unordered list using bullet points.

Note that every list type must be a one-element `character` vector containing one of the codes listed above. Specifying any other value for list type results in an error.

- `Report` for other functions adding contents to an HTML report

Examples
```r
## Not run:
report <- createReport("example.html", "Example", init.configuration = TRUE)
recipe <- list("Sift flour in a bowl", "Add sugar and mix", "Add milk and mix")
rnb.add.list(report, recipe, type="o")
## End(Not run)
```
rnb.add.paragraph

Description

Generates HTML code for a new paragraph in the specified report.

Usage

rnb.add.paragraph(report, txt, paragraph.class = NULL)

Arguments

report Report to write the text to.

 txt character vector (or array) storing the text to be written. The elements of this vector are concatenated without a separator.

paragraph.class CSS class definition of the paragraph. This must be either NULL (default) or one of:

"centered" This paragraph gives a formula or a short statement. Text is horizontally centered.

"note" This paragraph describes a note. Text is italic.

"task" This paragraph describes a task. Text is bold and bright red.

Report for other functions adding contents to an HTML report

Examples

## Not run:
report <- createReport("example.html", "Example", init.configuration = TRUE)
recipe <- c("A pessimist is a person who has had to listen to too many optimists.", "<i>Don Marquis</i>"

rnb.add.paragraph(report, txt)

## End(Not run)
Description

Adds a reference item to the given report.

Usage

```r
rnb.add.reference(report, txt)
```

Arguments

- `report`: Report to add a reference item to.
- `txt`: Text of the reference in the form of a non-empty character vector. The elements of this vector are concatenated without a separator.

Value

The modified report.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
report <- createReport("example.html", "Example", init.configuration = TRUE)
report <- rnb.add.reference(report, txt.reference)
txt <- c("This was shown in ", rnb.get.reference(report, txt.reference), ".")
rnb.add.paragraph(report, txt)
## End(Not run)
```
rnb.add.section  rnb.add.section

Description

Generates HTML code for a new section in the specified report.

Usage

rnb.add.section(report, title, description, level = 1L, collapsed = FALSE)

Arguments

report  Report to write the text to.
title    Section header. This must be a single-element character vector.
description  Human-readable paragraph text of the section in the form of a character vector. Elements of this vector are concatenated without a separator to form the full description. Set this to NULL if the section does not (yet) contain text.
level    Section level as a single integer. It must be one of 1, 2 or 3, denoting section, subsection and sub-subsection, respectively.
collapsed  Flag indicating if the contents of this section is to be initially collapsed. Possible values are TRUE (the section is not visible), FALSE (default, the section is expanded) and "never" (the section cannot be collapsed or expanded).

Value

The modified report.

Author(s)

Yassen Assenov

See Also

Report for other functions adding contents to an HTML report

Examples

## Not run:
report <- createReport("example.html", "Example", init.configuration = TRUE)
report <- rnb.add.section(report, "Introduction", "This is how it's done.")

## End(Not run)
rnb.add.table

Description

Generates HTML code for a table in the specified report.

Usage

rnb.add.table(report, tdata, row.names = TRUE, first.col.header = FALSE,
  indent = 0, tag.attrs = c(class = "tabdata"), thead = NULL,
  tcaption = NULL, na = "<span class="disabled">n/a</span>")

Arguments

report  Report to write the text to.
tdata   Matrix or data frame to be presented in HTML form. Column names, if present,
         are used to define table columns. If this table contains 0 (zero) rows or 0
         columns, calling this function has no effect.
row.names Flag indicating if row names should also be printed. If this parameter is TRUE
          and tdata defines row names, these are printed in the left-most column and
          are displayed as header cells. Keep in mind that data.frames always define
          row names.
first.col.header Flag indicating if all cells in the first column must be displayed as header cells.
         Note that, if both this parameter and row.names are TRUE, and tdata con-
         tains row names, the constructed HTML table will have 2 columns of header
         cells.
indent   Default indentation, in number of tabulation characters, to apply to HTML tags.
         This indentation is also applied to thead.
tag.attrs Named character vector specifying the list of attributes to be set to the
         <table> element. Setting this to NULL or an empty character vector dis-
         ables attributes.
thead    character vector storing a table header to include. This can, for example, be a character
         that defines column widths. Every element in this vector is written on a separate
         line, applying the indentation given by indent.
tcaption Text to include as a caption below the table, or NULL if the table does not contain
         caption.
na       character to be used for printing NA values in the table. This parameter is not considered
         when printing thead or the table’s column names.

Author(s)

Yassen Assenov

See Also

rnb.add.tables for adding a listing of tables; Report for other functions adding contents to
an HTML report
Description

Generates HTML code for a listing of tables (of which only one is visible at any moment) in the specified report.

Usage

rnb.add.tables(report, tables, setting.names, selected.table = 1L, indent = 2L, ...)

Arguments

- **report**: Report to write the text to.
- **tables**: Non-empty list of tables, each one represented by a `data.frame` or `matrix`. The names of this list are used as table identifiers; each one consists of elements separated by underscore character (_).
- **setting.names**: List of table name element descriptors. Every variable elements in the table names must be included in this list.
- **selected.table**: Index of the table to be initially selected in this listing.
- **indent**: Default indentation, in number of tabulation characters, to apply to every table.
- **...**: Other parameters passed to `rnb.add.table`.

Value

The modified report.

Author(s)

Yassen Assenov

See Also

`rnb.add.table` for adding a single table to a report; `Report` for other functions adding contents to an HTML report
rnb.annotation.size

Description

Gets the size, in number of genomic elements, of the specified annotation.

Usage

rnb.annotation.size(type = "CpG", assembly = "hg19")

Arguments

type Name of annotation. Control probe annotations are not accepted.
assembly Genome assembly of interest. See rnb.get.assemblies for the list of supported genomes.

Value

integer vector showing the number of elements the specified annotation contains per chromosome. The names of the vector are the names of rnb.get.chromosomes for the given genome assembly. Chromosomes that are not covered by the annotation have their respective value set to 0 (zero).

Author(s)

Yassen Assenov

See Also

rnb.region.types for a list of supported region annotations

Examples

## Not run:
library(RnBeads.hg19)
rnb.annotation.size("probes450")

## End(Not run)
rnb.annotation2data.frame

Description
Transform the specified site, probe or region annotation to data.frame.

Usage
rnb.annotation2data.frame(annotation.table, add.names = TRUE)

Arguments
annotation.table  Annotation in the form of non-empty GRangesList object, as returned by rnb.get.annotation.
add.names  Flag indicating if element names should be extracted and returned also as a column named "ID" in the resulting data.frame. Note that element names, if present, are set to be the row names of the table.

Value
Annotation in the form of a single data.frame. The columns in this table include, among other, "Chromosome", "Start" and "End".

Author(s)
Yassen Assenov

Examples
## Not run:
library(RnBeads.hg19)
head(rnb.annotation2data.frame(rnb.get.annotation("probes450")))

## End(Not run)

---

rnb.beta2mval

Description
Transforms beta values to M values, adjusting for +infinity and -infinity.

Usage
rnb.beta2mval(betas, epsilon = 1e-05)
Arguments

betas    numeric vector or matrix of beta values to be transformed.
epsilon  Single numeric in the range [0, 0.5], giving the threshold of beta values to use when adjusting for potential M values close to +infinity or -infinity. Setting this parameter to 0 (zero) disables stabilization; in which case M values of -infinity or +infinity could be returned.

Value

The calculated and adjusted M values.

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
mvals <- rnb.beta2mval(meth(rnb.set.example))
summary(mvals)
## End(Not run)
```

Description

Creates an HTML index file that contains listing of all available RnBeads reports. If no known reports are found in the specified directory, no index is created.

Usage

```r
rnb.build.index(dir.reports, fname = "index.html",
                 dir.configuration = "configuration", open.index = TRUE)
```

Arguments

- **dir.reports**: Directory that contains HTML reports generated by RnBeads modules. If this directory does not exist, is a regular file, is inaccessible, or does not contain any recognizable HTML report files, this function does not generate an HTML index file and produces an error or a warning message.
- **fname**: One-element character vector specifying the name of the index file to be generated. See the Details section for restrictions on the name. The file will be created in `dir.reports`. If such a file already exists, it will be overwritten.
dir.configuration
Subdirectory that hosts configuration files shared by the reports. This must be a character vector of length one that gives location as a path relative to dir.reports. Strong restrictions apply to the path name. See the description of the createReport function for more details.

open.index
Flag indicating if the index should be displayed after it is created. If this is TRUE, rnb.show.report is called to open the generated HTML file.

Details
In order to ensure independence of the operating system, there are strong restrictions on the name of the index file. It can consist of the following symbols only: Latin letters, digits, dot (.), dash (-) and underline (_). The extension of the file must be one of htm, html, xhtml or xml. The name must not include paths, that is, slash (/) or backslash (\) cannot be used. In addition, it cannot be any of the recognized RnBeads report file names.

Value
Names of all HTML report files that were referenced in the newly generated index, invisibly. The order of the file names is the same as the one they are listed in the index. If no known reports are found in the given directory, the returned value is an empty character vector.

Author(s)
Yassen Assenov

See Also
rnb.run.analysis, rnb.initialize.reports

description
calls the destructor of an RnBSet, RnBeadSet or RnBeadRawSet object conditionally on whether the enforce.destroy.disk.dumps option is enabled.

Usage
rnb.call.destructor(object, ...)

Arguments
object
  object to be destroyed

Value
  invisible TRUE
rnb.color.legends

Description

Creates a figure in the given report that contains one or more color legends.

Usage

rnb.color.legends(report, legends, fprefix = ifelse(is.character(legends),
"legend", "legend_"), description = "Color legend.", setting.names = NULL,
size.factor = 3)

Arguments

- **report**: Report to contain the legend figure. This must be an object of type `Report`.
- **legends**: Color legend in the form of a non-empty character vector. Element names denote legend labels, and the elements themselves specify colors. This parameter can also be a list of color legends. Special restrictions apply to the names of the list elements, see `Details`.
- **fprefix**: File name or prefix for the plot files.
- **description**: Text of the figure description. See the corresponding parameter in `rnb.add.figure` for more details.
- **setting.names**: One-element list containing a plot file descriptor, when `legends` is a list. See the corresponding parameter in `rnb.add.figure` for more details. If this is set to `NULL` (default), the list is automatically created using `names(legends)` (when `legends` is a list), or as an empty list (when `legends` is a vector).
- **size.factor**: Relative size, in inches of the plots. Legends are displayed in columns of up to 10 items; each column is effectively a square with the specified size.

Details

In case `legends` specifies multiple legends in the form of a list, `names(legends)` are appended to `fprefix` to generate file names. In order to ensure independence of the operating system, there are strong restrictions on these names. They can consist of the following symbols only: Latin letters, digits, dot (.), dash (−) and underline (_).

Value

The modified report.

Author(s)

- Yassen Assenov
Description

Computation of correlations and permutation-based p-values for detecting quality-associated batch effects.

Usage

rnb.execute.batch.qc(rnb.set, pcoordinates, permutations = NULL)

Arguments

- **rnb.set**: HumanMethylation450K dataset as an object of type `RnBeadSet`.
- **pcoordinates**: Coordinates of the samples of `rnb.set` in the principal components space, as returned by `rnb.execute.dreduction`.
- **permutations**: Matrix of sample index permutations, as returned by `rnb.execute.batcheffects`. If this parameter is `NULL`, permutation-based p-values are not calculated.

Value

`NULL` if no principal components for batch analysis are specified (`rnb.getOption("exploratory.principal.components") == 0`); otherwise, a hierarchical structure of matrices in the form of a nested list. The root branches are represented by the elements "correlations" and "pvalues". Every element is a list of control probe types; each type is in turn a list of up to two matrices of correlations between probe values and principal components - one for the probes on the green channel and one for the red channel. Note that the "pvalues" branch is not returned when `permutations` is `NULL`.

Author(s)

Pavlo Lutsik

Description

Performs tests for association between traits and principal components.

Usage

rnb.execute.batcheffects(rnb.set, pcoordinates = NULL)
Arguments

rnb.set     Methylation dataset as an object of type inheriting RnBSet.
pcoordinates Coordinates of the samples of rnb.set in the principal components space, as returned by rnb.execute.dreduction.

Value

Results of attempted tests for associations in the form of a list with up to three elements:

"permutations" integer matrix of index permutations. The number of rows in the matrix is N - the number of samples in rnb.set. Every column in this matrix denotes a sample permutation; the first column is the sequence 1 to N. This element is included only when rnb.getOption("exploratory.correlation.permutations") is non-zero and there are numeric traits to be tested.

"pc" List of four matrices named "failures", "tests", "correlations" and "pvalues". The rows in each of these matrices correspond to the first several principal components, and the columns - to selected traits. This element is not included in the returned list when pcoordinates is NULL.

"traits" List of four square symmetric matrices named "failures", "tests", "correlations" and "pvalues", containing information about the performed tests for pairwise trait association. This element is included only if two or more traits were tested.

rnb.run.exploratory for running the whole exploratory analysis module

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
regs <- c("sites", summarized.regions(rnb.set.example))
dreduction <- function(x) rnb.execute.dreduction(rnb.set.example, x)
pcoordinates <- lapply(regs, dreduction)
names(pcoordinates) <- regs
result <- rnb.execute.batcheffects(rnb.set.example, pcoordinates)
## End(Not run)
```

Description

Performs hierarchical clustering on the samples of the given dataset using multiple distance metrics and agglomeration methods for a single given region type.
Usage

rnb.execute.clustering(rnb.set, region.type = "sites")

Arguments

rnb.set Methylation dataset as an object of type inheriting RnBSet.
region.type the clustering is performed on methylation levels from regions of that type. see rnb.region.types for possible values.

Value

List of clustering results, whereby each element is an object of type RnBeadClustering. In case clustering cannot be performed, the return value is NULL. Reasons for a failure include, among others, the case when rnb.set contains less than 3 samples, or undefined distances between a pair of samples due to (too many) missing values in the respective methylation matrix.

Author(s)

Yassen Assenov

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
results <- rnb.execute.clustering(rnb.set.example, "promoters")
# List applied dissimilarity metrics
sapply(results, slot, "dissimilarity")
# List applied clustering algorithms
str(lapply(results, slot, "algorithm"))

## End(Not run)
rnb.execute.computeDiffMeth

Value
List of list of clustering results; each element corresponds to one region type and is a list of objects of type RnBeadClustering.

Author(s)
Fabian Mueller

See Also
rnb.execute.clustering for performing clustering using a single site or region type.

Description
computes differential methylation

Usage
rnb.execute.computeDiffMeth(x, pheno.cols, region.types = rnb.region.types.for.analysis(x), covg.thres = rnb.getOption("filtering.coverage.threshold"), pheno.cols.all.pairwise = rnb.getOption("differential.comparison.columns.all.pairwise"), columns.pairs = rnb.getOption("columns.pairing"), columns.adj = rnb.getOption("covariate.adjustment.columns"), adjust.sva = rnb.getOption("differential.adjustment.sva"), pheno.cols.adjust.sva = rnb.getOption("inferencetargets.sva"), adjust.celltype = rnb.getOption("differential.adjustment.celltype"), disk.dump = rnb.getOption("disk.dump.big.matrices"), disk.dump.dir = tempfile(pattern = "diffMethTables_"), ...)

Arguments
x  RnBSet object
pheno.cols  column names of the pheno slot in x on which the dataset should be partitioned. Those columns are required to be factors or logical. In case of factors, each group in turn will be compared to all other groups
region.types  which region types should be processed for differential methylation
covg.thres  coverage threshold for computing the summary statistics. See computeDiffTab.extended.site for details.
pheno.cols.all.pairwise  integer or character vector specifying the columns of pheno(x) on which all pairwise comparisons should be conducted. A value of NULL (default) indicates no columns.
columns.pairs  argument passed on to rnb.sample.groups. See its documentation for details.
Description

Removes all probes that belong to specific context from the given dataset.

Usage

```r
rnb.execute.context.removal(rnb.set,
    contexts = rnb.getOption("filtering.context.removal")
)```

Value

an `RnBDiffMeth` object. See class description for details.

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Sample_Group","Treatment"))
get.comparisons(dm)
## End(Not run)
```
Arguments

rnb.set: Methylation dataset as an object of type `RnBeadSet`.
contexts: Probe contexts to be filtered out.

Value

List of three or four elements:

- "dataset.before": Copy of rnb.set.
- "dataset": The (possibly modified) RnBeadSet object after performing the missing value removal.
- "filtered": integer vector storing the indices of all removed probes in dataset.before.
- "contexts": The value of the parameter contexts.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
contexts.to.ignore <- c("CC", "CAG", "CAH")
rnb.set.filtered <- rnb.execute.context.removal(rnb.set.example, contexts.to.ignore)$dataset
identical(rnb.set.example, rnb.set.filtered) # FALSE
## End(Not run)
```

rnb.execute.ct.estimation

rnb.execute.ct.estimation

Description

Perform the estimation of the cell type contributions in each analyzed sample.

Usage

```r
rnb.execute.ct.estimation(rnb.set, cell.type.column = NA,
  test.max.markers = NA, top.markers = 500, method = "houseman1",
  verbose = TRUE)
```

Arguments

- rnb.set: object of class `RnBSet`
- cell.type.column: integer index or character identifier of a column in sample annotation table of rnb.set which gives the mapping of samples to reference cell types
- test.max.markers: maximal amount of CpG positions to use for marker selection
The only supported method is the one from Houseman et al BMC Bioinformatics 2012

Value

object of class CellTypeInferenceResult

Author(s)

Pavlo Lutsik

Description

Performs principal component analysis (PCA) and multi-dimensional scaling (MDS) of the samples in the given methylation dataset.

Usage

rnb.execute.dreduction(rnb.set, target = "sites")

Arguments

rnb.set Methylation dataset as an object of type inheriting RnBSet. This dataset must contain at least four samples.

target character singleton specifying the level of DNA methylation information. If this is "sites", the DNA methylation information for the individual sites or probes is analyzed. Otherwise, this should be one of the supported region types, as returned by rnb.region.types.

Details

Row names in the returned matrices are sample identifiers, determined based on the package option "identifiers.column". See RnBeads Options for more information on this option.

Value

Results of the dimension reduction in the form of a list with the following elements:

pca Results of the PCA as returned by the function prcomp.

mds List of two elements - "manhattan" and "euclidean", each of which is a two-column matrix storing the coordinates of the samples in a two-dimensional space. The matrices are computed using the function isoMDS.
Author(s)
Yassen Assenov

See Also
rnb.run.exploratory for running the whole exploratory analysis module

Examples
```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
regs <- c("sites", summarized.regions(rnb.set.example))
dreduction <- function(x) rnb.execute.dreduction(rnb.set.example, x)
pcoordinates <- lapply(regs, dreduction)
names(pcoordinates) <- regs
str(pcoordinates)
## End(Not run)
```

Description
Exports (selected) methylation tables of the given dataset to comma-separated value files.

Usage
```
rnb.execute.export.csv(rnb.set, output.location, region.types = rnb.getOption("export.types"))
```

Arguments
```
  rnb.set     Methylation dataset as an object of type inheriting RnBSet.
  output.location character or Report specifying the output directory. If this is a report, the output directory is set to be a subdirectory named csv of the report’s data directory. Set this parameter to the empty string (""), or NA to use the current working directory. If the given path does not exist, this function attempts to create it.
  region.types character vector indicating region types to be exported.
```

Details
The names of the generated output files are formed by the prefix "betas_", followed by a number between 1 and length(region.types). The extension is .csv or .csv.gz, depending on the value of the RnBeads option "gz.large.files". Any such files that already exist in the output directory, are overwritten.

There are several reasons why a certain output file cannot be (fully) generated. Examples for failures are listed below:
The corresponding region type is invalid.

The corresponding region type is not supported by the dataset. If the type is loaded in RnBeads, use the `summarize.regions` method prior to calling this function, in order to include the support of this region type in the dataset.

Due to security restrictions, the creation of files in the output directory is not allowed.

A file or directory with the same name exists and cannot be overwritten.

The disk is full or the user quota is exceeded.

Value

Character vector containing the names of the files to which data were exported; prepended by `output.location`. In case a certain region type could not be exported (see the Details section), the corresponding element of this vector is `NA`.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.execute.export.csv(rnb.set.example, "", summarized.regions(rnb.set.example))
## End(Not run)
```

Description

Calculates a table summarizing the effect of the applied filtering procedures.

Usage

```r
rnb.execute.filter.summary(old.set, new.set)
```

Arguments

- `old.set` Methylation dataset before filtering as an object of type inheriting `RnBSet`
- `new.set` Methylation dataset after filtering as an object of type inheriting `RnBSet`

Details

This function expects that the sites and samples in `new.set` are subsets of the sites and samples in `old.set`, respectively. If this is not the case, it exists with an error.
Value

A matrix summarizing the number of removed and retained sites, samples, and (optionally) reliable and unreliable measurements.

Author(s)

Yassen Assenov

See Also

rnb.run.preprocessing for running the whole preprocessing module

Description

Infers the gender of every sample in the given Infinium 450k dataset, based on average signal intensity values on the autosomes and the sex chromosomes.

Usage

rnb.execute.gender.prediction(rnb.set)

Arguments

rnb.set Methylation dataset as an object of type RnBeadRawSet.

Value

The possibly modified dataset. If gender could be predicted, the sample annotation table is enriched with two more columns - "Predicted Male Probability" and "Predicted Gender".

Author(s)

Yassen Assenov

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.set.example <- rnb.execute.gender.prediction(rnb.set.example)
table(rnb.set.example[, "Predicted Gender"])

## End(Not run)
rnb.execute.greedycut

Description

Executes the Greedycut procedure for probe and sample filtering based on the detection p-values, and calculates statistics on its iterations.

Usage

rnb.execute.greedycut(rnb.set,
  rc.ties = rnb.getOption("filtering.greedycut.rc.ties"))

Arguments

rnb.set HumanMethylation450K dataset as an object of type RnBeadSet.
rc.ties Flag indicating what the behaviour of the algorithm should be in case of ties between values of rows (probes) and columns (samples). See the corresponding parameter in greedycut.filter.matrix for more details.

Value

NULL if rnb.set does not contain a matrix of detection p-values, or if all p-values denote reliable measurements. Otherwise, a list of the following elements:

"infos" Table summarizing the iterations of the algorithm, as returned by greedycut.filter.matrix.
"statistics" Additional statistics on all iterations, as returned by greedycut.get.statistics.
"iteration" Number of Greedycut iterations + 1 applied to the dataset, that is, a value of 1 indicates that the dataset was not modified.
"sites" Indices of all sites to be removed.
"samples" Indices of all samples to be removed.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
greedy.result <- rnb.execute.greedycut(rnb.set.example)
# Number of applied iterations
greedy.result$iteration

## End(Not run)
```
Description

Removes methylation sites with a coverage larger than 100 times the 95-percentile of coverage in each sample.

Usage

rnb.execute.high.coverage.removal(rnb.set)

Arguments

rnb.set Methylation dataset as an object of type inheriting \texttt{RnBiseqSet}.

Value

list of two elements:

"dataset" The (possibly) modified dataset after retaining sites on autosomes only.
"filtered" integer vector storing the indices of all removed sites.

Author(s)

Fabian Mueller

Description

Loads the data from the specified type and encapsulates it in either an \texttt{RnBSet}-inheriting object

Usage

rnb.execute.import(data.source, data.type = rnb.getOption("import.default.data.type"), dry.run = FALSE, verbose = TRUE)

Arguments

data.source non-empty character vector or list specifying the location of the data items. The expected format depends on the data.type that is given. See the Details section.

data.type type of the input data; must be one of \"idat.dir\", \"data.dir\", \"data.files\", \"GS.report\", \"GEO\" or \"rnb.set\".

dry.run if TRUE and data.type is \"bs.bed.dir\", only a test data import is performed and first 10,000 lines are read from each BED file

verbose flag specifying whether diagnostic output should be written to the console or to the RnBeads logger in case the latter is initialized
Details

The interpretation of `data.source` depends on the value of `data.type` and is summarized in the following table:

<table>
<thead>
<tr>
<th>data.type</th>
<th>Type of <code>data.source</code></th>
<th>Maximal length of <code>data.source</code></th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;infinium.idat.dir&quot;</td>
<td>list or character</td>
<td>2</td>
<td>(1) Directory containing IDAT files; (2) a sample annotation table as a data.frame or the name of the corresponding file</td>
</tr>
<tr>
<td>&quot;infinium.data.dir&quot;</td>
<td>character</td>
<td>1</td>
<td>Directory containing data tables in plain text format.</td>
</tr>
<tr>
<td>&quot;infinium.data.files&quot;</td>
<td>character</td>
<td>2..4</td>
<td>The character vector containing Genome Studio report files.</td>
</tr>
<tr>
<td>&quot;infinium.GS.report&quot;</td>
<td>character</td>
<td>1</td>
<td>Genome Studio report file</td>
</tr>
<tr>
<td>&quot;infinium.GEO&quot;</td>
<td>character</td>
<td>1</td>
<td>GEO identifier or downloaded series matrix file</td>
</tr>
<tr>
<td>&quot;bs.bed.dir&quot;</td>
<td>list or character</td>
<td>1..3</td>
<td>(1) Directory with BED files each giving a DNA methylation profile of a sample; (2) a sample annotation table as a data.frame or the name of the corresponding file; (3) number of the sample annotation sheet column containing the file names. One of these columns should contain the file name. For this reason the file names in the sample annotation sheet should be given with extensions (&quot;.bed&quot;, &quot;cov&quot; etc).</td>
</tr>
<tr>
<td>&quot;rnb.set&quot;</td>
<td>RnBSet</td>
<td>1</td>
<td>object of class inheriting from RnBSet</td>
</tr>
</tbody>
</table>

Value

Loaded data as an object of type `RnBSet` (when the input data type is "data.dir", "data.files" or "GEO") or of type `MethyLumiSet` (when the data type is "idat.dir" or "GS.report").

Author(s)

Pavlo Lutsik

See Also

`read.data.dir`, `read.idat.files`, `read.GS.report`, `read.geo`, `read.bed.files`  
#'

Examples

```r
## Not run:
# Directory where your data is located
data.dir <- "~/RnBeads/data/Ziller2011_PLoSGen_450K"
idat.dir <- file.path(data.dir, "idat")
sample.annotation <- file.path(data.dir, "sample_annotation.csv")
data.source <- c(idat.dir, sample.annotation)
rnb.set <- rnb.execute.import(data.source = data.source, data.type = "idat.dir")

## End(Not run)
```

Description

Replaces all low coverage sites by NA.

Usage

```r
rnb.execute.low.coverage.masking(rnb.set,
covg.threshold = rnb.getOption("filtering.coverage.threshold"))
```
Arguments

- **rnb.set**: Methylation dataset as an object of type inheriting `RnBSet`.
- **covg.threshold**: Threshold for minimal acceptable coverage, given as a non-negative integer value. All methylation measurements with lower coverage than this threshold are set to NA. If this parameter is 0, calling this method has no effect.

Value

List of three elements:

- "dataset.before": Copy of `rnb.set`.
- "dataset": The (possibly) modified dataset after retaining sites on autosomes only.
- "mask": A logical matrix of dimension `meth(rnb.set, type="sites")` indicating which methylation values have been masked.

Author(s)

Fabian Mueller

---

**rnb.execute.na.removal**

**Description**

Removes all probes with missing value (if such exists) from the given dataset.

**Usage**

```r
rnb.execute.na.removal(rnb.set, threshold = rnb.getOption("filtering.missing.value.quantile"))
```

**Arguments**

- **rnb.set**: Methylation dataset as an object of type inheriting `RnBSet`.
- **threshold**: Maximum quantile of NAs allowed per site. This must be a value between 0 and 1.

**Value**

List of four or five elements:

- "dataset.before": Copy of `rnb.set`.
- "dataset": The (possibly modified) dataset after performing the missing value removal.
- "filtered": Integer vector storing the indices (in beta matrix of the unfiltered dataset) of all removed sites.
- "threshold": Copy of `threshold`.
rnb.execute.normalization

Author(s)
Yassen Assenov

Examples
```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.set.filtered <- rnb.execute.na.removal(rnb.set.example, 0)$dataset
identical(meth(rnb.set.example), meth(rnb.set.filtered)) # TRUE
## End(Not run)
```

Description
Performs normalization of the provided HumanMethylation450 data set.

Usage
```r
rnb.execute.normalization(object,
method = rnb.getOption("normalization.method"),
bgcorr.method = rnb.getOption("normalization.background.method"),
verbose = TRUE)
```

Arguments
- `object` Methylation dataset as an object of type `MethyLumiSet` or `RnBSet`.
- `method` Normalization method, must be one of "none", "illumina", "swan", "minfi.funnorm", "bmiq", or wm.* where * stands for one of the methods implemented in `watermelon` package. Note that the execution of methods SWAN and minfi.funnorm requires packages `minfi` and `IlluminaHumanMethylation450kmanifest`. The BMIQ method requires the package `RPMM`. The `wm.*` methods naturally require `watermelon`.
- `bgcorr.method` Character singleton specifying which background subtraction should be used. Only methods implemented in the `methylumi` package are supported at the moment, namely methylumi.noob, methylumi.goob and methylumi.doob. See Triche et al. for detailed description of the methods.
- `verbose` flag specifying whether diagnostic output should be written to the console or to the RnBeads logger in case the latter is initialized

Value
Normalized dataset as an object of type `RnBeadSet`.

Author(s)
Pavlo Lutsik
rnb.execute.quality

References

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.set.norm<-rnb.execute.normalization(rnb.set.example, method="illumin", bgcor.method

## End(Not run)
```

**rnb.execute.quality**

**Description**

Performs quality control calculations on the loaded DNA methylation data set.

**Usage**

```r
rnb.execute.quality(object, type = "sites",
qc.coverage.plots = rnb.getOption("qc.coverage.plots"), verbose = TRUE)
```

**Arguments**

- `object`: Methylation dataset as an object of class `RnBeadSet`, `RnBeadRawSet` or `RnBiseqSet`.
- `type`: character vector of length 1 giving the type of genomic regions for which the quality control information is summarized.
- `qc.coverage.plots`: Flag indicating if sequencing coverage information is summarized and returned. This parameter is considered only when `object` is of type `RnBiseqSet`.
- `verbose`: Flag specifying whether diagnostic output should be written to the console or to the RnBeads logger in case the latter is initialized.

**Details**

Currently, summarizing coverage for `RnBiseqSet` object is the only available function.

**Value**

- `RnBeadSet` object with imputed quality control information

**Author(s)**

Pavlo Lutsik
rnb.execute.sex.removal

Description
Removes all sites in sex chromosomes from the given dataset.

Usage
rnb.execute.sex.removal(rnb.set)

Arguments
rnb.set Methylation dataset as an object of type inheriting RnBSet.

Value
List of three elements:
"dataset.before" Copy of rnb.set.
"dataset" The (possibly) modified dataset after retaining sites on autosomes only.
"filtered" integer vector storing the indices (in beta matrix of the unfiltered dataset) of all removed probes.

Author(s)
Yassen Assenov

Examples
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.set.filtered <- rnb.execute.sex.removal(rnb.set.example)$dataset
identical(meth(rnb.set.example), meth(rnb.set.filtered)) # FALSE
## End(Not run)

rnb.execute.snp.removal

Description
Removes all probes overlapping with single nucleotide polymorphisms (SNPs) from the given dataset.

Usage
rnb.execute.snp.removal(rnb.set, snp = rnb.getOption("filtering.snp"))
rnb.execute.sva

rnb.execute.sva

Arguments

rnb.set Methylation dataset as an object of type inheriting RnBSet.
snp Criterion for the removal of sites or probes based on overlap with SNPs. Possible values are "no", "3", "5", "any" or "yes". See the documentation of rnb.options for a detailed explanation of the procedures these values encode.

Value

list of four elements:

"dataset.before" Copy of rnb.set.
"dataset" The (possibly) modified dataset object after removing probes that overlap with SNPs.
"filtered" integer vector storing the indices (in beta matrix of the unfiltered dataset) of all removed sites or probes.
"snp" The value of the snp parameter.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.set.filtered <- rnb.execute.snp.removal(rnb.set.example, "any")$dataset
identical(meth(rnb.set.example), meth(rnb.set.filtered)) # FALSE
## End(Not run)
```

rnb.execute.sva

rnb.execute.sva

Description

Conduct Surrogate Variable Analysis (SVA) on the beta values of an RnBSet for given target variables

Usage

rnb.execute.sva(rnb.set, cmp.cols = rnb.getOption("inference.targets.sva"), columns.adj = rnb.getOption("covariate.adjustment.columns"), assoc = TRUE, numSVmethod = rnb.getOption("inference.sva.num.method"))
**Arguments**

- **rnb.set**  
The RnBSet object on which the SVA should be conducted
- **cmp.cols**  
a vector of sample annotation column names which will be the targets of the SVA.
- **columns.adj**  
Column names in the table of phenotypic information to be used for confounder adjustment.
- **assoc**  
a flag indicating whether association information with principal components and other sample annotation should be returned
- **numSVmethod**  
method to estimate the number of surrogate variables. Passed to sva.

**Value**

An object of class `SvaResult`: basically a list containing the following elements:

- **num.components**  
a vector storing the number of detected SVs for each target variable
- **sva.performed**  
a vector storing whether SVA was performed on a target variable and whether more than 0 SVs were found
- **targets**  
a vector storing the names of the target variables
- **components**  
a list storing for each target variable a matrix containing the sample-wise SVs as rows
- **assoc**  
a special object containing association information of SVs with principal components and sample annotations typically only used `rnb.section.sva`.

**Author(s)**

Fabian Mueller

**Examples**

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
sva.obj <- rnb.execute.sva(rnb.set.example,c("Sample_Group","Treatment"),numSVmethod="be")
sva.obj$sva.performed
sva.obj$num.components
rnb.set.mod <- set.covariates.sva(rnb.set.example, sva.obj)
has.covariates.sva(rnb.set.example,"Sample_Group")
has.covariates.sva(rnb.set.mod, "Sample_Group")
has.covariates.sva(rnb.set.mod,"Treatment")

## End(Not run)
```
Description

export RnBSet to various output data formats

Usage

\[ rnb.execute.tnt(rnb.set, out.dir, exp.bed = rnb.getOption("export.to.bed"), \]
\[ exp.trackhub = rnb.getOption("export.to.trackhub"), \]
\[ region.types = rnb.getOption("export.types"), \ldots \]

Arguments

- **rnb.set**: RnBSet object
- **out.dir**: output directory.
- **exp.bed**: A character vector indicating which data types should be exported to UCSC. Possible values in the vector are `bigBed` and `bigWig`. If NULL, UCSC export is disabled
- **exp.trackhub**: file types which should be exported to a trackhub structure.
- **region.types**: a character vector indicating region types to be exported
- **\ldots**: Arguments passed to `rnb.export.to.trackhub`

Value

a list containing information on the export

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.execute.tnt(rnb.set.example,tempdir())
## End(Not run)
```
Description

Removes all sites or probes with low variability from the given dataset.

Usage

\[
\text{rnb.execute.variability.removal(rnb.set,} \\
\text{    min.deviation = rnb.getOption("filtering.deviation.threshold")})
\]

Arguments

- \textit{rnb.set}: Methylation dataset as an object of type inheriting \texttt{RnBSet}.
- \textit{min.deviation}: Threshold for standard deviation per site. This must be a scalar between 0 and 1. All sites, for which the standard deviation of methylation values (for all samples in \texttt{rnb.set}) is lower than this threshold, will be filtered out.

Value

List of four elements:

- "\texttt{dataset.before}": Copy of \texttt{rnb.set}.
- "\texttt{dataset}": The (possibly modified) dataset after removing sites with low variability.
- "\texttt{filtered}": integer vector storing the indices (in beta matrix of the unfiltered dataset) of all removed sites.
- "\texttt{threshold}": The value of the given parameter \texttt{min.deviation}.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.set.filtered <- rnb.execute.variability.removal(rnb.set.example, 0.01)
## End(Not run)
```
rnb.export.all.annotation

**Description**

Wrapper for exporting all annotation sets

**Usage**

```r
rnb.export.all.annotation(out.dir, types = c("CpG", 
    rnb.region.types(assembly)), assembly = "hg19", format = "bed")
```

**Arguments**

- `out.dir` The directory to write the files to
- `types` One-element character vector giving the name of the region annotation.
- `assembly` Genome assembly of interest. See `rnb.get.assemblies` for the list of supported genomes.
- `format` output format. currently only "bed" is supported.

**Author(s)**

Fabian Mueller

**Examples**

```r
## Not run:
logger.start(fname=NA)
runb.export.all.annotation(tempdir(),c("genes","promoters"))
## End(Not run)
```

rnb.export.annotation

**Description**

Export the annotation to a defined format (currently only bed is supported)

**Usage**

```r
rnb.export.annotation(fname, type, assembly = "hg19", format = "bed")
```
Arguments

fname  One-element character vector giving the name of the file to contain the annotation data. If this file already exists, it will be overwritten.
type   One-element character vector giving the name of the region annotation.
assembly Genome assembly of interest. See `rnb.get.assemblies` for the list of supported genomes.
format  Output format. Currently only "bed" is supported.

Author(s)

Fabian Mueller

Examples

## Not run:
rnb.export.annotation(tempfile(pattern="promoters",fileext=".bed"),"promoters")
## End(Not run)

Description

Data exported to a format compatible with the FaST-LMM-EWASher tool for cell-mixture adjustment. See Zou, J., et al., Nature Methods, 2014 for further details on the tool.

Usage

```
rnb.export.to.ewasher(rnb.set, out.dir, reg.type = "sites", ...)
```

Arguments

- rnb.set  Object of class `RnBSet`
- out.dir  output directory. If not existing, it will be created and all exported files will be placed here. If existing, this function results in an error.
- reg.type  region type to be exported
- ...  passed on to `get.comparison.info`

Value

a list containing information on the export

Author(s)

Fabian Mueller
Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.export.to.ewasher(rnb.set.example,tempfile(pattern="forEwasher"))
## End(Not run)
```

Description

convert an RnBSet object to a UCSC-style track hub.

Usage

```r
rnb.export.to.trackhub(rnb.set, out.dir, reg.type = "sites",
data.type = "bigBed", ...)
```

Arguments

- `rnb.set`: Object of class RnBSet
- `out.dir`: output directory. If not existing, it will be created. otherwise files in that directory are overwritten.
- `reg.type`: region type to be converted
- `data.type`: either "bigBed" or "bigWig"
- `...`: parameters passed on to the track hub generating procedure

Details

During execution the RnBSet is converted to bed files. If the operating system is supported (currently Unix and MacOS only) these are automatically converted to bigBed files. If your operating system is not supported, you need to create them manually (see the UCSC Genome Browser documentation for details). For details on UCSC track hubs see the UCSC tracks help page.

Value

a list containing information on the export

Author(s)

Fabian Mueller
Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.export.to.trackhub(rnb.set.example,tempdir())

## End(Not run)
```

Description

given a region types, assigns sites to regions and determines relative positions of sites in the assigned region

Usage

```r
rnb.find.relative.site.coord(rnb.set, region.type, extend.by = 0.33)
```

Arguments

- `rnb.set`: RnBSet object
- `region.type`: Region type for which the coordinates are computed
- `extend.by`: A number between 0 and 1 specifying the percentage by which a region is extended in order to capture methylation information before region start and after region end

Value

a data frame containing the site index, the assigned region index and the relative coordinate The relative coordinate is 0 if the site’s coordinate is identical to the region start coordinate and 1 if identical to the regions end coordinate and scaled inbetween. Coordinates can be less than 0 or larger than 1 if a site is in the upstream or downstream flanking region respectively

Author(s)

Fabian Mueller
Description

Extracts the requested annotation for the given genome.

Usage

rnb.get.annotation(type = "CpG", assembly = "hg19")

Arguments

type Name of annotation.
assembly Genome assembly of interest. See rnb.get.assemblies for the list of supported genomes.

Details

When the returned value is of type GRangesList, it defines the genomic positions of the requested sites, probes or regions. Identifiers, if present, can be obtained using the names method. Strand information is also included when applicable. Any additional annotation is stored as metadata in the respective GRanges objects.

Value

Probe, site or region annotation table. If the specified type refers to control probes, the returned value is a data.frame listing all respective control probes. Otherwise, this function returns an object of type GRangesList - a list of consistent GRanges objects, one per chromosome.

Author(s)

Fabian Mueller

See Also

rnb.set.annotation for adding annotation; rnb.region.types for all loaded region types in a genome assembly

Examples

```r
## Not run:
rnb.get.annotation("promoters")
## End(Not run)
```
rnb.get.assemblies

Description

Gets the supported genome assemblies.

Usage

rnb.get.assemblies()

Value

All supported genome assemblies in the form of a character vector. These are "hg19", "mm10", "mm9" and "rn5".

Author(s)

Yassen Assenov

Examples

## Not run:
"hg19" %in% rnb.get.assemblies()
## End(Not run)

rnb.get.chromosomes

Description

Gets the chromosome names supported for the specified assembly.

Usage

rnb.get.chromosomes(assembly = "hg19")

Arguments

assembly Genome assembly of interest. See rnb.get.assemblies for the list of supported genomes.

Value

class character vector of supported chromosomes for the specified genome assembly. The elements of the vector follow the Ensembl convention ("1", "2", ...), and the names of this vector - the convention of the UCSC Genome Browser ("chr1", "chr2", ...).
Author(s)
  Pavlo Lutsik

Examples
  ## Not run:
  "chrX" %in% names(rnb.get.chromosomes())
  ## End(Not run)

rnb.get.directory  rnb.get.directory

Description
  Gets the location of the given report-specific directory.

Usage
  rnb.get.directory(report, dir = c("data", "images", "images-high", "pdfs"),
                    absolute = FALSE)

Arguments
  report  Report of interest.
  dir     Type of directory to get. Must be one of "data", "images", "images-high" or "pdfs".
  absolute Flag indicating if the absolute path of the directory is to be returned. If this is FALSE, the directory name is returned relative to the report’s HTML file location.

Value
  Path of the requested directory as a single-element character vector.

Author(s)
  Yassen Assenov

See Also
  Report for functions adding contents to an HTML report

Examples
  ## Not run:
  report <- createReport("example.html", "Example", init.configuration = TRUE)
  rnb.get.directory(report, "data")
  ## End(Not run)
Description

Gets the mapping information used for a region type. These are structures used to map regions to the genomic loci (or Infinium probes) that target them.

Usage

```r
rnb.get.mapping(region.type, target.type, assembly = "hg19")
```

Arguments

- `region.type`: Region type. The built-in types are "cpgislands", "genes", "promoters" and "tiling".
- `target.type`: Target type for sites.
- `assembly`: Genome assembly of interest. See `rnb.get.assemblies` for the list of supported genomes.

Value

A list of mapping structures, one per chromosome. Every mapping structure is an object of type `IRanges` and stores the range of indices of all sites contained in the respective region. Regions that do not contain sites are left out of the mapping.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
promoters2probes <- rnb.get.mapping("promoters", "probes450")
promoters2probes["chr21"]
## End(Not run)
```

Description

Creates a string that points to the given reference item in the specified report.

Usage

```r
rnb.get.reference(report, txt)
```
rnb.get.reliability.matrix

Description

Gets a matrix of reliability indications for every measurement in the given dataset.

Usage

rnb.get.reliability.matrix(rnb.set, row.names = FALSE)

Arguments

rnb.set Methylation dataset as an object of type inheriting RnBSet.
row.names Flag indicating of row names are to be generated in the result.

Value

logical matrix in which every row corresponds to a CpG site or probe and every column - to a patient. If the dataset does not contain coverage or detection p-value information, the returned value is NULL.
rnb.infinium.control.targets

Author(s)

Yassen Assenov

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.options(identifiers.column = "Sample_ID")
str(rnb.get.reliability.matrix(rnb.set.example))
## End(Not run)
```

Description

Extracts all control probe types in the HumanMethylation450 assay.

Usage

```r
rnb.infinium.control.targets(target = "probes450")
```

Arguments

target

A singleton of type character, specifying the microarray platform. "probes450" and "probes27" correspond to HumanMethylation450 respectively HumanMethylation27 microarrays

Value

character vector of control targets.

Author(s)

Pavlo Lutsik

Examples

```r
## Not run:
"NEGATIVE" %in% rnb.infinium.control.targets()
## End(Not run)
```
Description

Creates a new directory to host HTML reports and copies the shared configuration files.

Usage

```r
rnb.initialize.reports(dir.reports, dir.configuration = "configuration")
```

Arguments

- `dir.reports`: Directory to host report files. This must be a character of length one that specifies a non-existent path, as this method attempts to create it.
- `dir.configuration`: Subdirectory to host configuration files shared by the reports. This must be a character of length one that gives location as a path relative to `dir.reports`. Also, strong restrictions apply to the path name. See the description of the `createReport` function for more details. This method creates the directory and copies configuration files that define cascading style sheet (CSS) definitions and Javascript functions used by the HTML reports.

Value

`TRUE` if the report directory was successfully created and the configuration files were copied to the specified location; `FALSE` otherwise.

Author(s)

Yassen Assenov

See Also

- `createReport` for initializing an HTML report

Examples

```r
## Not run:
dir.reports <- "/infinium_studies/cancer_study/reports"
if (!rnb.initialize.reports(dir.reports)) {
  cat("ERROR: Could not initialize configuration in ", dir.reports, "\n", sep = "")
}
## End(Not run)
```
Description
Checks if the specified text is an option name.

Usage
rnb.is.option(txt)

Arguments
txt Potential option name. This should be a one-element character vector.

Value
TRUE if the specified parameter is a valid analysis option name; FALSE otherwise.

Author(s)
Yassen Assenov

See Also
rnb.options for getting and setting option values

Examples
## Not run:
rnb.is.option("logging") # TRUE
rnb.is.option("Logging") # FALSE

## End(Not run)

Description
 Loads a previously saved custom region annotation from a binary (RData) file.

Usage
rnb.load.annotation(fname, type)
Arguments

fname  One-element character vector giving the name of the file that contains the annotation data.
type  One-element character vector giving the name of the region annotation. If this annotation is already available, it will be overwritten for the current session.

Details

If the region annotation cannot be loaded from the specified location, this function exits with an error message in the form "unable to load object from ...". This could happen, for example, when fname does not refer to a valid RData file, or the file cannot be accessed due to security restrictions.

If the file is loaded in the current session, but no annotation was added, the function returns invisibly one of the following short failure messages:

"invalid format" The RData file does not store exactly the following three objects - assembly, regions, and mapping, or they are not of the expected type.
"unsupported assembly" The specified assembly is unknown.
"invalid format of regions" The specified region annotation table is invalid.
"invalid format of mappings" The specified region mapping tables are invalid.

Value

Invisibly, TRUE if the annotation was loaded successfully; an error message if the objects in the given file do not encode an annotation.

Author(s)

Yassen Assenov

See Also

rnb.save.annotation for saving annotation to a binary file; rnb.set.annotation for loading an annotation from a BED file.
Arguments

fname  File listing the identifiers, one per line.
verbose Flag indicating if messages are to be printed. If the values is TRUE and a logger is initialized, this function adds a message to the log.

Value

The loaded list of identifiers, or NULL if fname could not be open.

Author(s)

Yassen Assenov

See Also

logger.start for initializing a logger

Description

Creates a plot, using ggplot2, with a single text message.

Usage

rnb.message.plot(txt)

Arguments

txt  Text to be plotted.

Value

The newly initialized ggplot instance.

Author(s)

Yassen Assenov

Examples

## Not run:
x11(width = 5, height = 5)
rnb.message.plot("Missing data")
## End(Not run)
### rnb.mval2beta

**Description**

Transforms M values to beta values.

**Usage**

```r
rnb.mval2beta(mvals)
```

**Arguments**

- `mvals` numeric vector or matrix of M values to be transformed.

**Value**

The calculated beta values.

**Author(s)**

Pavlo Lutsik

**Examples**

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
mvals <- rnb.beta2mval(meth(rnb.set.example))
bvals <- rnb.mval2beta(mvals)
all((bvals-meth(rnb.set.example))<1e-10)
## End(Not run)
```

---

### rnb.options

**RnBeads Options**

**Description**

Allows the user to set and examine a variety of RnBeads global options. They affect the way in which the package computes and displays its results.

**Usage**

```r
rnb.options(...)  
rnb.getOption(x)
```
Arguments

... Option names as characters, or new option values given in the form name = value.
x Option name in the form of a character vector of length 1.

Details

Invoking rnb.options() with no arguments returns a list with the current values of the options. To access the value of a single option, one should use, e.g., rnb.getOption("filtering.greedycut"), rather than rnb.options("filtering.greedycut") which is a list of length one. Also, only a limited set of options is available (see below). Attempting to get or set the value of a non-existing option results in an error.

Value

For rnb.getOption, the current value for x. For rnb.options(), a list of all RnBeads options and their current values. If option names are given, a list of all requested options and their values. If option values are set, rnb.options returns the previous values of the modified options, invisibly.

Options used in RnBeads

analysis.name = NULL One-element character vector storing a short title of the analysis. If specified, this name appears at the page title of every report.
logging = TRUE Flag indicating if logging functionality is enabled in the automatic runs of the pipeline.
email = NULL Email address associated with the analyses.
assemble = "hg19" Genome assembly to be used. Currently only important for bisulfite mode. The supported genomes returned by the function rnb.get.assemblies.
analyze.sites = TRUE Flag indicating if analysis on site or probe level is to be conducted. Note that the preprocessing module always operates on the site level (only), regardless of the value of this option.
region.types = NULL Region types to carry out analysis on, in the form of a character vector. NULL (default value) signifies that all available region annotations (as returned by rnb.region.types) are summarized upon loading and normalization, and the other modules analyze all regions summarized in the dataset. If this option is set to an empty vector, analysis on the region level is skipped.
region.aggregation = "mean" Aggregation function to apply when calculating the methylation value for a region based on the values of the CpGs associated with that region. Accepted values for this function are "min", "max", "mean" (default), "median", "sum", "coverage.weighted". The last method is applicable only for sequencing-based methylation datasets. It computes the weighted average of the values of the associated CpGs, whereby weights are calculated based on the coverages of the respective sites.
region.subsegments = 0 If a number larger than 1 is specified, RnBeads will subdivide each region specified in the region.types option into subsegments containing on average region.subsegments sites per subsegment. This is done by clustering the sites within each regions according to their genomic coordinates. These subsegments are then used for subsequent analysis. Use cautiously as this will significantly increase the runtime of the pipeline.
region.subsegments.types = NULL The region types to which subsegmentation will be applied. Defaults to region.types when set to NULL.
identifiers.column = NULL Column name or index in the table of phenotypic information to be used when plotting sample identifiers. If this option is NULL, it points to a non-existing column or a column that does not list IDs, the default identifiers are used. These are the row names of the sample phenotype table (and the column names of the beta value matrix).

colors.category = c("#1B9E77","#D95F02",...) character vector of length 2 or more giving the color scheme for displaying categorical trait values in plots. RnBeads denotes missing values (NA) by grey, therefore, it is not recommended to include shades of grey in this vector. The default value of this option is the result of the "Dark2" palette of RColorBrewer with 8 values.

colors.gradient = c("#132B43","#56B1F7") character vector of length 2 or more giving the color scheme for displaying continuous (gradient) trait values in plots. RnBeads interpolates between the color values.

min.group.size = 2 Minimum number of samples each subgroup defined by a trait, in order for this trait to be considered in the methylation profiles and in the differential methylation modules. This must be a positive integer.

max.group.count = NULL Maximum number of subgroups defined by a trait, in order for this trait to be considered in the methylation profiles and in the differential methylation modules. This must be an integer of value 2 or more. As a special case, a value of NULL (default) indicates that the maximum number of subgroups is the number of samples in an analysis minus 1, i.e. traits with all unique values will be ignored.

replicate.id.column = NULL Column name in the sample annotation table that indicates sample replicates. Replicates are expected to contain the same value. Samples without replicates should contain unique or missing values. If this option is NULL (default), replicate handling is disabled.

gz.large.files = FALSE Flag indicating whether large output files should be compressed (in .gz format).

import = TRUE Flag controlling whether data import report should be generated. This option be set to FALSE only when the provided data source is an object of type RnBSet, i.e. the data has been previously loaded by RnBeads.

import.default.data.type = "infinium.idat.dir" Type of data assumed to be supplied by default (Infinium 450k microarray). For sequencing data set this to bs.bed.dir and save the options. See rnb.execute.import for further details.

import.table.separator = "," Separator used in the plain text data tables. See rnb.execute.import for details.

import.bed.style = "BisSNP" Preset for bed-like formats. "BisSNP", "Encode", "EPP", "bismark" are currently supported. See the RnBeads vignette and the FAQ section on the website for more details.

import.bed.columns Column indices in the supplied BED file with DNA methylation information. These are represented by a named integer vector, in which the names are: "chr", "start", "end", "strand", "meth", "coverage", "c" and "t". These names correspond the columns for chromosome, start position, end position, strand, methylation degree, read coverage, number of reads with C and number of reads with T, respectively. Methylation degree and/or read coverage, if not specified, are inferred from the values in the columns "c" and "t". Further details and examples of BED files can be found in Section 4.1 of the RnBeads vignette.

import.bed.frame.shift = 1 Singleton of type integer specifying the frame shift between the coordinates in the input BED file and the corresponding genomic reference. This (integer) value is added to the coordinates from the BED file before matching the methylation sites to the annotated ones.
import.bed.test = TRUE  Perform a small loading test, by reading 1000 rows from each BED file, after which normal loading is performed. See RnBeads vignette and the FAQ section on the website for more details.

import.bed.test.only = FALSE  Perform only the small loading test, and skip loading all the data.

preprocessing = TRUE  Flag controlling whether the data should be preprocessed (whether quality filtering and in case of Infinium microarray data normalization should be applied).

normalization = NULL  Flag controlling whether the data should be normalized and normalization report generated. Setting this to NULL (default) enables this step for analysis on Infinium datasets, but disables it in case of sequencing-based datasets. Note that normalization is never applied in sequencing datasets; if this flag is enabled, it will lead to a warning message.

normalization.method = "swan"  Normalization method to be applied, or "none". Multiple normalization methods are supported: "illumina" - methylumi-implemented Illumina scaling normalization; "swan" (default) - SWAN-normalization by Gordon et al., as implemented in minfi; "bmiq" - beta-mixture quantile normalization method by Teschendorff et al; as well as "wm.dansen", "wm.nasen", "wm.betaqn", "wm.nanet", "wm.nanes", "wm.danes", "wm.danet", "wm.daten", "wm.daten2", "wm.tost", "wm.fuks" and "wm.swan" - all normalization methods implemented in the watermelon package. When setting this option to a specific algorithm, make sure its dedicated package is installed.

normalization.background.method = "methylumi.noob"  A character singleton specifying which background subtraction is to be performed during normalization. The methylumi background correction methods are supported. The following values are accepted: "none", "methylumi.noob", "methylumi.goob" and "methylumi.lumi".

normalization.plot.shifts = TRUE  Flag indicating if the report on normalization should include plots of shifts (degrees of beta value correction).

qc = TRUE  Flag indicating if the quality control module is to be executed.

qc.boxplots = TRUE  [Infinium 450k] Add boxplots for all types of quality control probes to the quality control report. The boxplots give signal distribution across samples.

qc.barplots = TRUE  [Infinium 450k] Add barplots for each quality control probes to the quality control report.

qc.negative.boxplot = TRUE  [Infinium 450k] Add boxplot of negative control probe intensities for all samples.

qc.snp.distances = TRUE  [Infinium 450k] Flag indicating if intersample distances based on the beta values of SNP probes are to be displayed. This can help identify or validate genetically similar or identical samples.

qc.snp.boxplot = FALSE  [Infinium 450k] Add boxplot of beta-values for the SNP-calling probes. Can be useful for detection of sample mix-ups.

qc.snp.barplot = FALSE  [Infinium 450k] Add bar plots of beta-values for the SNP-calling probes in each profiled sample.

qc.sample.batch.size = 50  [Infinium 450k] Maximal number of samples included in a single quality control barplot and negative control boxplot.

qc.coverage.plots = FALSE  [Bisulfite sequencing] Add genome-wide sequencing coverage plot for each sample.

qc.coverage.threshold.plot = 1:10  [Bisulfite sequencing] Values for coverage cutoffs to be shown in a coverage thresholds plot. This must be an integer vector of positive values. Setting this to an empty vector disables the coverage thresholds plot.
qc.coverage.histograms = FALSE  [Bisulfite sequencing] Add sequencing coverage histogram for each sample.

qc.coverage.violins = FALSE  [Bisulfite sequencing] Add sequencing coverage violin plot for each sample.

filtering.whitelist = NULL Name of a file specifying site or probe identifiers to be whitelisted. Every line in this file must contain exactly one identifier. The whitelisted sites are always retained in the analysed datasets, even if filtering criteria or blacklisting requires their removal. For Infinium studies, the file must contain Infinium probe identifiers. For bisulfite sequencing studies, the file must contain CpG positions in the form "chromosome:coordinate" (1-based coordinate of the cytosine), e.g. chr2:48607772. Unknown identifiers are silently ignored.

filtering.blacklist = NULL Name of a file specifying site or probe identifiers to be blacklisted. Every line in this file must contain exactly one identifier. The blacklisted sites are removed from the analysed datasets as a first step in the preprocessing module. For Infinium studies, the file must contain Infinium probe identifiers. For bisulfite sequencing studies, the file must contain CpG positions in the form "chromosome:coordinate" (1-based coordinate of the cytosine), e.g. chr2:48607772. Unknown identifiers are silently ignored.

filtering.context.removal = c("CC","CAG",...) character vector giving the list of probe context types to be removed as a filtering step. Possible context values are "CC", "CG", "CAG", "CAH", "CTG", "CTH" and "Other". Probes in the second context measure CpG methylation; the last context denotes probes dedicated to SNP detection. Setting this option to NULL or an empty vector effectively disables the step of context-specific probe removal.

filtering.snp = "3" Removal of sites or probes based on overlap with SNPs. The accepted values for this option are:

"no" no SNP-based filtering;
"3" filter out a probe when the last 3 bases in its target sequence overlap with SNP;
"5" filter out a probe when the last 5 bases in its target sequence overlap with SNP;
"any" or "yes" filter out a CpG site or probe when any base in its target sequence overlaps with SNP.

Bisulfite sequencing datasets operate on sites instead of probes, therefore, the values "3" and "5" are treated as "yes".

filtering.sex.chromosomes.removal = FALSE  Flag indicating if the removal of probes located on sex chromosomes should be performed as a filtering step.

filtering.missing.value.quantile = 1 Number between 0 and 1, indicating the fraction of allowed missing values per site. A site is filtered out when its methylation beta values are NAs in a larger fraction of samples than this threshold. Setting this option to 1 (default) retains all sites, and thus effectively disables the missing value filtering step in the preprocessing module. If this is set to 0, all sites that contain missing values are filtered out.

filtering.coverage.threshold = 5 Threshold for minimal acceptable coverage. This must be a non-negative value. Setting this option to 0 (zero) effectively considers any known or unknown read coverage for sufficiently deep.

filtering.low.coverage.masking = FALSE  Flag indicating whether methylation values for low coverage sites should be set to missing. In combination with filtering.missing.value.quantile this can lead to the removal of sites.

filtering.high.coverage.outliers = FALSE  [Bisulfite sequencing mode] Flag indicating whether methylation sites with a coverage of more than 10 times the 95-percentile of coverage should be removed.
filtering.greedycut = TRUE  Flag indicating if the Greedycut procedure should be run as part of the preprocessing module.

filtering.greedycut.pvalue.threshold = 0.05  Threshold for the detection p-value to be used in Greedycut. This is a value between 0 and 1. This option has effect only when filtering.greedycut is TRUE.

filtering.greedycut.rc.ties = "row"  Indicator of what the behaviour of Greedycut should be in case of ties between the scores of rows (probes) and columns (samples). The value of this option must be one of "row", "column" or "any"; the last one indicating random choice. This option has effect only when filtering.greedycut is TRUE.

filtering.deviation.threshold = 0  Threshold used to filter probes based on the variability of their assigned beta values. This must be a real value between 0 and 1, denoting minimum standard deviation of the beta values in one site across all samples. Any sites that have standard deviation lower than this threshold are filtered out. Note that sites with undetermined variability, that is, sites for which there are no measurements (all beta values are NAs), are retained. Setting this option to 0 (default) disables filtering based on methylation variability.

inference = FALSE  Flag indicating if the covariate inference analysis module is to be executed.

inference.targets.sva = character()  Column names in the sample annotation table for which surrogate variable analysis (SVA) should be conducted. An empty vector (default) means that SVA is skipped.

inference.reference.methylome.column = character()  Column name in the sample annotation table giving the assignment of samples to reference methylomes. The target samples should have NA values in this column.

inference.max.cell.type.markers = 10000  A number of most variable CpGs which are tested for association with the reference cell types.

inference.top.cell.type.markers = 500  The number of top cell type markers used for determining cell type contributions to the target DNA methylation profiles using the projection method of Houseman et al.

inference.sva.num.method = "leek"  Name of the method to be used for estimating the number of surrogate variables. must be either 'leek' or 'be', See sva function for details.

exploratory = TRUE  Flag indicating if the exploratory analysis module is to be executed.

exploratory.columns = NULL  Traits, given as column names or indices in the sample annotation table, to be used in the exploratory analysis. These traits are used in multiple steps in the module: they are visualized using point types and colors in the dimension reduction plots; tested for strong correlations and associations with principal components in a methylation space; used to define groups when plotting beta distributions and/or inter-sample methylation variability. The default value of this parameter - NULL - indicates that columns should be automatically selected; see rnb.sample.groups for how this is done.

exploratory.top.dimensions = 0  Number of most variable probes, sites or regions to select prior to performing dimension reduction techniques and tests for associations. Preselection can significantly reduce the running time and memory usage in the exploratory analysis module. Setting this number to zero (default) disables preselection.

exploratory.principal.components = 8  Maximum number of principal components to be tested for associations with other factors, such as control probe states and sample traits. This must be an integer value between 0 and 10. Setting this option to 0 disables such tests.

exploratory.correlation.pvalue.threshold = 0.01  Significance threshold for a p-value resulting from applying a test for association. This is a value between 0 and 1.
exploratory.correlation.permutations = 10000  Number of permutations in tests performed to check for associations between traits, and between control probe intensities and coordinates in the principal component space. This must be a non-negative integer. Setting this option to 0 disables permutation tests.

exploratory.correlation.qc = TRUE  [Infinium 450k] Flag indicating if quality-associated batch effects should be studied. This amounts to testing for associations between intensities of quality control probes and principal components. This option has effect only when exploratory.principal.components is non-zero.

exploratory.beta.distribution = TRUE  Flag indicating whether beta value distributions for sample groups and probe or site categories should be computed.

exploratory.intersample = TRUE  Flag indicating if methylation variability in sample groups should be computed as part of the exploratory analysis module.

exploratory.deviation.plots = NULL  Flag indicating if the inter-sample methylation variability step in the exploratory analysis module should include deviation plots. Deviation plots show intra-group methylation variability at the covered sites and regions. Setting this option to NULL (default) enables deviation plots on Infinium datasets, but disables them in case of sequencing-based datasets, because their generation can be very computationally intensive. This option has effect only when exploratory.intersample is TRUE.

exploratory.clustering = "all"  Which sites should be used by clustering algorithms in the exploratory analysis module. RnBeads performs several algorithms that cluster the samples in the dataset. If this option is set to "all" (default), clustering is performed using all sites; a value of "top" indicates that only the most variable sites are used (see the option exploratory.clustering.top.sites); and "none" disables clustering.

exploratory.clustering.top.sites = 1000  Number of most variable sites to use when visualizing heatmaps. This must be a non-empty integer vector containing positive values. This option is ignored when exploratory.clustering is "none".

exploratory.clustering.heatmaps.pdf = FALSE  Flag indicating if the generated methylation value heatmaps in the clustering section of the exploratory analysis module should be saved as PDF files. Enabling this option is not recommended for large values of exploratory.clustering.top.sites (more than 200), because heatmaps might generate very large PDF files.

exploratory.region.profiles = NULL  Region types for generating regional methylation profiles. If NULL (default), regional methylation profiles are created only for the region types that are available for the targeted assembly and summarized in the dataset of interest. Setting this option to an empty vector disables the region profiles step in the exploratory analysis module.

exploratory.gene.symbols = NULL  A list of gene symbols to be used for custom locus profiling. Locus views will be generated for these genes.

exploratory.custom.loci.bed = NULL  Path to a bed file containing custom genomic regions. Locus views will be generated for these regions.

differential = TRUE  Flag indicating if the differential methylation module is to be executed.

differential.site.test.method = "limma"  Method to be used for calculating p-values on the site level. Currently supported options are "ttest" for a (paired) t-test and "limma" for a linear modeling approach implemented in the limma package for differential expression in microarrays.

differential.permutations = 0  Number of permutation tests performed to compute the p-value of rank permutation tests in the differential methylation analysis. This must be a non-negative integer. Setting this option to 0 (default) disables permutation tests for rank permutations. Note that p-values for differential methylation are computed and also considered for the ranking in any case.
differential.comparison.columns = NULL Column names or indices in the table of the sample annotation table to be used for group definition in the differential methylation analysis. The default value - NULL - indicates that columns should be automatically selected. See `rnb.sample.groups` for how this is done. By default, the comparisons are done in a one vs. all manner if there are multiple groups defined in a column.

differential.comparison.columns.all.pairwise = NULL Column names or indices in the table of sample annotation table to be used for group definition in the differential methylation analysis in which all pairwise comparisons between groups should be conducted (the default is one vs all if multiple groups are specified in a column). Caution: for large numbers of sample groups this can lead to combinatorial explosion and thus to huge runtimes. A value of NULL (default) indicates that no column is selected for all pairwise comparisons explicitly. If specified, the selected columns must be a subset of the columns that will be selected according to the `differential.comparison.columns` option.

covariate.adjustment.columns = NULL Column names or indices in the table of phenotypic information to be used for confounder adjustment in the differential methylation analysis. Currently this is only supported for `differential.site.test.method=="limma"`.

columns.pairing = NULL A NAMED vector containing for each column name for which paired analysis should be performed (say columnA) the name or index of another column (say columnB) in which same values indicate the same pairing. columnA should be the name of the value columnB in this vector. For more details see `rnb.sample.groups`.

differential.adjustment.sva = TRUE Flag indicating if the differential methylation analysis should account for Surrogate Variables. If TRUE, RnBeads looks for overlaps between the `differential.comparison.columns` and `inference.targets.sva` options and include the surrogate variables as confounding factors only for these columns. In other words, it will only have an effect if the corresponding inference option (see `inference.targets.sva` option for details) is enabled. Currently this is only supported for `differential.site.test.method=="limma"`.

differential.adjustment.celltype = TRUE Should the differential methylation analysis account for celltype using the reference based Houseman method. It will only have an effect if the corresponding inference option is enabled (see `inference.reference.methylome.column` option for details). Currently this is only supported for `differential.site.test.method=="limma"`.

differential.enrichment = FALSE Flag indicating whether Gene Ontology (GO)-enrichment analysis is to be conducted on the identified differentially methylated regions.

export.to.bed = TRUE Flag indicating whether the data should be exported to bed files.

export.to.trackhub = c("bigBed","bigWig") character vector specifying which data types should be exported to Track hub directories. Possible values in the vector are "bigBed" and "bigWig". When this options is set to NULL, track hub export is disabled. Note that if "bigBed" is contained in this option, bed files are created automatically.

export.to.csv = FALSE Flag indicating whether methylation value matrices are to be exported to comma-separated value (CSV) files.

export.to.ewasher = FALSE Flag indicating whether methylation values and differential methylation analysis settings should be exported to a format compatible with FaST-LMM-EWASher, a tool for adjusting for cell-type compositions. See Zou, J., et al., Nature Methods, 2014 for further details on the tool.

export.types = "sites" character vector of sites and region names to be exported. If NULL, no region methylation values are exported.

disk.dump.big.matrices = FALSE Flag indicating whether big tables should be stored on disk rather than in main memory in order to keep memory requirements down. May slow down analysis!
logging.exit.on.error = FALSE  Flag indicating if the active R session should be terminated when an error is encountered during execution.

distribution.subsample = 1000000  When plotting methylation value distributions, this threshold specifies the number of observations drawn per group. Distributions are estimated and plotted based on these random subsamples. This approach can significantly reduce the memory requirements of the preprocessing and exploratory analysis modules, where methylation value distributions are plotted. Setting this to 0 disables subsampling. More information is presented the Details section of rnb.step.betadistribution.

enforce.memory.management = FALSE  Flag indicating whether in some places of the code memory management should actively being enforced in order to achieve a better memory profile. I.e. garbage collection, variable removal is conducted actively. May slow down analysis.

enforce.destroy.disk.dumps = FALSE  Flag indicating whether disked dumped big matrices (see disk.dump.big.matrices option) should actively be deleted when RnBSets are modified. You should switch it to TRUE when disk.dump.big.matrices is TRUE and the amount of hard drive space is also limited.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
str(rnb.options())
rnb.getOption("filtering.greedyCut")
## End(Not run)
```

Description

Exports all option values to an XML document.

Usage

```r
rnb.options2xml(pretty = TRUE)
```

Arguments

pretty  Flag indicating if the document should be formatted to be easily readable. For example, if this is set to TRUE (default), every element is located on separate line. Formatting does not affect the validity of the generated XML tree.

Value

XML document in the form of a character that encodes all options and their current values.
rnb.performance.profile

Author(s)
Yassen Assenov

Examples
## Not run:
cat(rnb.options2xml(), file = "rnbeads_options.xml")
## End(Not run)

rnb.performance.profile

Description
Enables one of the pre-installed analysis option profiles.

Usage
rnb.performance.profile(data.type = "450k", profile)

Arguments
data.type Type of dataset targeted; this must be one of "450k" (default) or "bs".
profile Option profile; this must be one of "minimal", "moderate" or "full".

Author(s)
Pavlo Lutsik

rnb.plot.beta.comparison

Description
Draws plots that compare two distributions of beta values.

Usage
rnb.plot.beta.comparison(beta.values, fprefix, report = NULL,
qq.length = 501L,
points.per.group = rnb.getOption("distribution.subsample"))
Arguments

beta.values  Two beta value sequences in the form of a named list of two non-empty vectors of type double. If any of the vectors contains NAs, this method may exit with an error.
fprefix    File name prefix for the plots. This function appends the suffixes "_density", "_histogram" and "_qq" to this prefix.
report     Report to which the plots are to be added.
qq.length  Positive integer value showing the number of quantiles to be calculated and presented in the generated Q-Q plot.
points.per.group Maximum number of values to use in plotting a group’s distribution. Groups that contain more observations than this threshold are subsampled. Setting this parameter to a value less than 2 disables subsampling.

Value

List of all generated plots, each being an object ot type ReportPlot.

Author(s)

Yassen Assenov

Description

plot beta value distributions given probe categories

Usage

rnb.plot.betadistribution.probeCategories(beta.matrix, probe.cat, annotation = "Group", color.legend = NULL, log.str = NULL, points.per.group = rnb.getOption("distribution.subsample"))

Arguments

beta.matrix  Beta values in the form of a non-empty matrix of type double. Rows in this matrix must correspond to Infinium probes, and columns - to samples.
probe.cat    factor vector of length nrow(beta.matrix) corresponding to the probe categories.
annotation   Name of the annotation being visualized, in the form of a character vector of length 1.
color.legend Color legend to use in the form of a character vector with element names. The values in this vector should encode colors. All values in probe.cat must be present in the names of this color legend. If this parameter is NULL, a default color legend is be constructed.
log.str      string specifying more details for the log file
**rnb.plot.betadistribution.sampleGroups**

points.per.group

the targeted number of points per group. Set this to a value < 1 to disable sub-
sampling. More information in the Details section of `rnb.step.betadistribution`

**Value**

The plot as a `ggplot2` object.

**Author(s)**

Fabian Mueller

**See Also**

`rnb.plot.betadistribution.sampleGroups`

**Examples**

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
meth.mat <- meth(rnb.set.example)
probe.types <- annotation(rnb.set.example)[, "Design"]
rnb.plot.betadistribution.probeCategories(meth.mat, probe.types, annotation="Infinium probe")
## End(Not run)
```

**Description**

Plots beta value distributions given a sample grouping.

**Usage**

```r
rnb.plot.betadistribution.sampleGroups(beta.matrix, sample.group.inds, annotation = "Group", log.str = NULL, points.per.group = rnb.getOption("distribution.subsample"))
```

**Arguments**

- `beta.matrix`: Beta values in the form of a non-empty matrix of type `double`. Rows in this matrix must correspond to Infinium probes, and columns - to samples.

- `sample.group.inds`: Named list that contains indices for the samples contained in the groups in `beta.matrix`. The number of groups is determined by the length of the list, and its names are used as group names.

- `annotation`: Name of the annotation being visualized, in the form of a character vector of length 1.
rnb.plot.biseq.coverage

Description

Plots the sequencing coverage of the RnBiseqSet object across the genomic coordinate

Usage

rnb.plot.biseq.coverage(rnbs.set, sample, type = "sites",
writeToFile = FALSE, numeric.names = FALSE, covg.lists = NULL, ...)

Arguments

rnbs.set RnBiseqSet object
sample unique sample identifier. In case rnb.getOption("identifiers.column")
is not NULL, sample should attain values from the corresponding column, or
colnames(meth(rnb.set)) otherwise
type character singleton. If site the coverage information is plotted for each
methylation site. Otherwise should be one of the regions returned by rnb.region.types
writeToFile flag specifying whether the output should be saved as ReportPlot
rnb.plot.biseq.coverage.hist

numeric.names
  if TRUE and writeToFile is TRUE substitute the plot options in the plot file name with digits

covg.lists
  if available, the output of rnb.execute.quality

... other arguments to createReportPlot

Value

plot as an object of type ReportPlot if writeToFile is TRUE and of class ggplot otherwise.
 TODO add examples

Author(s)
Pavlo Lutsik

Description
Plots the histograms of the coverage

Usage

rnb.plot.biseq.coverage.hist(rnbs.set, sample, type = "sites",
writeToFile = FALSE, numeric.names = FALSE, covg.max.percentile = 1,
...)

Arguments

rnbs.set RnBiseqSet object
sample unique sample identifier. In case rnb.getOption("identifiers.column") is not NULL, sample should attain values from the corresponding column, or colnames(meth(rnb.set)) otherwise

type character singleton. If site the coverage information is plotted for each methylation site. Otherwise should be one of the regions returned by rnb.region.types

writeToFile a flag specifying whether the output should be saved as ReportPlot
numeric.names
  if TRUE and writeToFile is TRUE substitute the plot options in the plot file name with digits

covg.max.percentile
  the maximum percentile of the coverage to be plotted

... other arguments to createReportPlot

Value

plot as an object of type ReportPlot if writeToFile is TRUE and of class ggplot otherwise.
 TODO add examples
rnb.plot.biseq.coverage.violin

Author(s)

Pavlo Lutsik

Description

Plots the violin plots of the coverage distribution

Usage

rnb.plot.biseq.coverage.violin(rnbs.set, samples, fname = NULL, type = "sites", covg.range = NULL, ...)

Arguments

rnbs.set RnBiseqSet object

samples unique sample identifiers. In case rnb.getOption("identifiers.column") is not NULL, samples should attain values from the corresponding column, or colnames(meth(rnb.set)) otherwise

fname base filename for the files to be plotted. If NULL, the plot will not be written to file

type character singleton. If site the coverage information is plotted for each methylation site. Otherwise should be one of the regions returned by rnb.region.types

covg.range Vector of length 2 specifying the range of coverage to be plotted. if NULL (default) the entire range will be plotted

... other arguments to createReportPlot

Value

plot as an object of type ReportPlot if writeToFile is TRUE and of class ggplot otherwise.

Author(s)

Fabian Mueller TODO add examples
Description

Per-sample bar plots of Illumina HumanMethylation control probes

Usage

rnb.plot.control.barplot(rnb.set, probe,
    sample.subset = 1:length(samples(rnb.set)), writeToFile = FALSE,
    numeric.names = FALSE, name.prefix = NULL, verbose = F, ...)

Arguments

rnb.set: RnBeadRawSet or RnBeadSet object with valid quality control information
probe: exact id of the control probe consisting of the control probe type (see rnb.plot.control.boxplot)
sample.subset: an integer vector specifying the subset of samples for which the plotting should be performed
writeToFile: flag specifying whether the output should be saved as ReportPlot
numeric.names: if TRUE and writeToFile is TRUE, substitute the plot options in the plot file name with digits
name.prefix: in case writeToFile is TRUE, a character singleton specifying a prefix to the variable part of the image file names
verbose: if TRUE additional diagnostic output is generated
...
other arguments to createReportPlot

Value

plot as an object of type ReportPlot if writeToFile is TRUE and of class ggplot otherwise.

Author(s)

Pavlo Lutsik

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
control.meta.data <- rnb.get.annotation("controls450")
ctrl.probe <- paste0(unique(control.meta.data[['Target']])[4], ".5")
print(ctrl.probe) # EXTENSION.5
rnb.control.barplot(rnb.set.example, ctrl.probe)

## End(Not run)
Description
Box plots of various control probes

Usage
rnb.plot.control.boxplot(rnb.set,
  type = rnb.infinium.control.targets(rnb.set@target)[1],
  writeToFile = FALSE, numeric.names = FALSE, ...)

Arguments
rnb.set RnBeadRawSet or RnBeadSet object with valid quality control information.
type type of the control probe; must be one of the "BISULFITE CONVERSION I", "BISULFITE CONVERSION II", "EXTENSION", "HYBRIDIZATION", "NEGATIVE", "NON-POLYMORPHIC", "NORM_A", "NORM_C", "NORM_G", "NORM_T", "SPECIFICITY I", "SPECIFICITY II", "STAINING", "TARGET REMOVAL".
writeToFile flag specifying whether the output should be saved as ReportPlot
numeric.names if TRUE and writeToFile is TRUE substitute the plot options in the plot file name with digits
... other arguments to createReportPlot

Value
plot as an object of type ReportPlot if writeToFile is TRUE and of class ggplot otherwise.

Author(s)
Pavlo Lutsik

Examples
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.plot.control.boxplot(rnb.set.example)
## End(Not run)
rnb.plot.coverage.thresholds

Description

Plots the number of remaining CpGs after applying different thresholds for coverage and support.

Usage

rnb.plot.coverage.thresholds(rnb.set, min.coverages, fname = NA, ...)

Arguments

rnb.set  Methylation dataset as an object of type RnBiseqSet.
min.coverages  Non-empty integer vector storing the unique positive cutoff values to be applied for minimal coverage. Names, if present, are interpreted as colors that must be used to denote the corresponding values.
fname  File name to save the generated plot to. See the Details section for restrictions.
...  Additional named parameters related to saving the plot to files. These can include: report, width, height, create.pdf, low.png and high.png. These parameters are ignored when fname is NULL or NA.

Details

If fname is specified, this function calls createReportPlot to save the plot to PDF and/or PNG files. See its documentation for information on acceptable file names. Additional parameters - report, width, height, etc. - can also be given. If image width is not specified, it is set to a value between 4.7 and 9.2 (inches), depending on the number of samples in the dataset. The default image height is fixed to 7.2.

Value

If fname is NULL or NA (default), the generated plot as an object of type ggplot2; otherwise, the initialized and closed ReportPlot object, invisibly.

Author(s)

Yassen Assenov
rnb.plot.ct.heatmap

Description

Plot contributions of the cell types

Usage

rnb.plot.ct.heatmap(ct.obj, type = "nonnegative", writeToFile = FALSE, ...)

Arguments

ct.obj Object of class CellTypeInferenceResult as returned by rnb.execute.ct.estimation.
type Type of cell type contributions to plot.
writeToFile If TRUE, the plot will be written to a file.
... Other arguments passed to createReportPlot.

Details

The cell type contributions are visualized as a heatmap

Value

If writeToFile=TRUE an object of class ReportPlot, or the plotted matrix otherwise

Author(s)

Pavlo Lutsik

rnb.plot.dreduction

Description

Creates a dimension reduction plot based on the methylation values of the given dataset.

Usage

rnb.plot.dreduction(rnb.set, plot.type = "pca", dimensions = 1:2,
  distance.metric = "euclidean", target = "sites", point.types = 0L,
  point.colors = 0L, legend.space = 2)
Arguments

- **rnb.set**: Methylation dataset as an object of type inheriting `RnBSet`. This dataset must contain at least four samples.
- **plot.type**: Type of plot to be created. This must be one of "pca" (projection to two principal components) or "mds" (multidimensional scaling to two dimensions). The section Details provides more details on how the dimension reduction techniques are applied.
- **dimensions**: Vector of two positive integer values giving the principle components to be shown in the horizontal and vertical axis of the plot. This parameter is considered only when `plot.type` is "pca".
- **distance.metric**: Distance metric to be applied when reducing the dimensionality of the methylation data. This must be one of "euclidean" or "manhattan". The second metric is supported only in multidimensional scaling.
- **target**: Site or region type to be used in the dimension reduction technique. This must be either "sites" (individual CpGs) or one of the region types summarized in `rnb.set`.
- **point.types**: Trait, specified as column name or index in the sample annotation table of `rnb.set`, to be used to define point types in the plot. Setting this parameter to zero (default) or to a trait that does not define categories results in all samples being displayed as filled circles. If this parameter specifies a column that can be used as sample identifiers, the plot displays the samples as identifiers instead of points.
- **point.colors**: Trait, specified as column name or index in the sample annotation table of `rnb.set`, to be used to define sample colors in the plot. Setting this parameter to zero (default) or to a trait that does not define categories results in all samples being displayed in black.
- **legend.space**: Width, in inches, of the space dedicated for legends that will be assigned on the right side of the plot. This parameter is considered only if legends are actually included, that is, if sample traits are mapped to point types and/or colors.

Details

The analysis option "exploratory.top.dimensions" controls whether dimension reduction is applied on all probes, sites or regions available in the given dataset, or only on the most variable ones. In case a trait is mapped to point types, the shapes to use are taken from the option "points.category". Similarly, the option "colors.category" determines which colors are used when mapping to color is applied. See `RnBeads Options` for more information on these options.

Value

The generated plot as an object of type `ggplot`. The object also contains an attribute "info", which is a list with the following elements:

- **Target**: Targeted sites or regions; the value of the parameter `target`.
- **Technique**: Dimension reduction technique applied; one of "PCA" or "MDS".
- **All**: Total number of sites or regions defining the high dimensional methylation space.
- **Missing**: Number of dimensions ignored because they contain (only) missing values.
- **Selected**: Number of dimensions used when applying a dimension reduction technique.
"Explained" Value between 0 and 1 showing the variance explained by the selected dimensions, as a fraction of the total variance of all dimensions.

Author(s)
Yassen Assenov

See Also

summarized.regions for listing all region types summarized in a dataset

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
pdf("PCA.pdf", width = 7.2, height = 5.2)
print(rnb.plot.dreduction(rnb.set.example, point.colors="Sample_Group"))
dev.off()

## End(Not run)

rnb.plot.locus.profile

Description
Computes methylation distributions for various region types and sample groups

Usage

rnb.plot.locus.profile(rnbSet, chrom, start, end, grps = NULL, plot.m.regions = NULL, plot.m.heatmap = TRUE, plot.m.smooth = TRUE, cvals.grps = rnb.getOption("colors.category"), cvals.meth = rnb.getOption("colors.meth"))

Arguments

rnbSet RnBSet object
chrom chromosome of window to plot
start start coordinate of window to plot
end end coordinate of window to plot
grps a list of indices for each group to be compared or NULL if no sample grouping information should be displayed
plot.m.regions character vector of region types whose methylation values should be displayed
If grps is not NULL the methylation values will be separated by sample groups.
plot.m.heatmap flag indicating whether sites methylation values should be displayed in a heatmap. If grps is not NULL the heatmaps will be separated by sample groups.
plot.m.smooth
flag indicating whether a scatterplot with smoothing curves should be displayed. If grps is not NULL the colors will be used to separate sample groups.
cvals.grps
colors to be used for the different groups
cvals.meth
colors to be used for methylation values and heatmaps

Value
a ggplot2 plot object containing the plot

Author(s)
Fabian Mueller

Examples
## Not run:
# see RnBeads vignette (section: 'Generating Locus Profile Plots') for examples
## End(Not run)

rnb.plot.marker.fstat
rnb.plot.marker.fstat

Description
Plot the the cell type marker selection based on the reference methylome data

Usage
rnb.plot.marker.fstat(ct.object, writeToFile = FALSE, ...)

Arguments
c.object
Object of class CellTypeInferenceResult as returned by rnb.execute.ct.estimation.
writeToFile
If TRUE, the plot will be written to a file.
... Other arguments to createReportPlot.

Details
The F-statistic values from the cell type association model (first part of eqn. (1) in [1]) are plotted in decreasing order for all tested CpG positions. A vertical line gives a cut-off for the number of selected cell type markers.

Value
if writeToFile=TRUE an object of class ReportPlot, and the plotted reordered F-statistics vector otherwise
Author(s)

Pavlo Lutsik

References

Description

Box plots of negative control probes

Usage

rnb.plot.negative.boxplot(rnb.set, sample.subset = 1:length(samples(rnb.set)), writeToFile = FALSE, name.prefix = NULL, ...)

Arguments

rnb.set RnBeadSet object with valid quality control information
sample.subset an integer vector specifying the subset of samples for which the plotting should be performed
writeToFile flag specifying whether the output should be saved as ReportPlot
name.prefix in case writeToFile is TRUE, a character singleton specifying a prefix to the variable part of the image file names
... other arguments to createReportPlot

Value

plot as an object of type ReportPlot if writeToFile is TRUE and of class ggplot otherwise.

rnb.plot.num.sites.covg

Description
plot the number of sites vs the 0.05, 0.5 (median) and 0.95 percentiles of coverage

Usage
rnb.plot.num.sites.covg(rnbs, addSampleNames = (length(samples(rnbs)) < 100))

Arguments
rnbs RnBseqSet object
addSampleNames should the sample names be added to the plot

Value
plot as an object of type ggpplot

Author(s)
Fabian Mueller

rnb.plot.pheno.categories

Description
Generates bar charts summarizing the categorical traits in a sample annotation table.

Usage
rnb.plot.pheno.categories(annotations, columns = NULL,
  fileprefix = "barchart_pheno", report = NULL,
  color.values = rnb.getOption("colors.category"))

Arguments
annotations Methylation dataset as an object of type inheriting RnBSet, or its sample annotations in the form of a data.frame. If this parameter is a dataset, the annotation information is extracted using the method pheno.
columns Optional: predefined column names (in the form of a character vector) or indices (an integer vector) to consider. All other columns in the annotation table will be ignored.
rnb.plot.region.profile.density

fileprefix character vector with one element storing the file name prefix of the output files, without the extension. Only a limited set of symbols is allowed to be used in this prefix.

report Report to contain the generated plots. If specified, this must be an object of type Report.

color.values Non-empty character vector containing the color scheme to be mapped to the categories defined in the annotation table. Colors are recycled if necessary, that is, if the length of this vector is smaller than the number of categories in a trait.

Details

This function identifies the traits that define sample subgroups and then generates one report plot per trait. Every report plot consists of two files. File names are formed by appending an index and file extension to fileprefix. Thus, the suffixes appended are "_1.pdf", "_1.png", "_2.pdf", "_2.png", ... Existing files with the generated filenames are overwritten.

Value

List of report plots. The names in this list are the column names in the annotation table that were selected for visualization. In case no suitable categorical traits are found among the provided annotations, this function returns an empty list.

Author(s)

Yassen Assenov

See Also

rnb.sample.groups for identifying traits in the annotation table that define sample subgroups;
createReportPlot for the allowed symbols to be used in fileprefix

Description

Plots the density of methylation levels across all regions of the specified type

Usage

rnb.plot.region.profile.density(rnb.set, sample, region.type = "", region.profile = NULL, extend.by = 0.33)
Arguments

- **rnb.set**: RnBSet object
- **sample**: Index or name of the sample for which the plot should be generated
- **region.type**: Region type for which the plot should be generated
- **region.profile**: Alternative to specifying `region.type`, the function can accept a region profile generated by the `rnb.find.relative.site.coord` function
- **extend.by**: A number between 0 and 1 specifying the percentage by which a region is extended in order to capture methylation information before region start and after region end

Value

A ggplot2 object for plotting the plot shows the density of methylation levels of sites across the specified region type for all regions of that type from 0 (region start) to 1 (region end). Sites in the flanking areas are also shown (coordinates <0 and >1).

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.plot.region.profile.density(rnb.set.example,1,"genes")
## End(Not run)
```

Description

Creates a composite plot showing the sample and groupwise smoothed estimates of methylation values across all regions of the specified type

Usage

```r
rnb.plot.region.profiles(rnb.set, group.index.list, region.type = "", region.profile = NULL, extend.by = 0.33, cvalues = rnb.getOption("colors.category"))
```
Arguments

rnb.set  RnBSet object

group.index.list  a list (preferably named) containing sample indices for each group a list of such lists is for instance generated by the rnb.sample.groups function.

region.type  Region type for which the plot should be generated

region.profile  Alternative to specifying region.type, the function can accept a region profile generated by the rnb.find.relative.site.coord function

extend.by  A number between 0 and 1 specifying the percentage by which a region is extended in order to capture methylation information before region start and after region end

cvalues  Color values that will be assigned to sample groups

Value

a ggplot2 object for plotting the plot shows the smoothed methylation levels of sites accross the specified region type for all regions of that type from 0 (region start) to 1 (region end). Sites in the flanking areas are also shown (coordinates <0 and >1). Smoothing is stratified by sample (dashed lines) and sample group (thick solid lines). Cubic splines are used for smoothing

Author(s)

Fabian Mueller

Examples

```r
## Not run:
#Careful: this might take a while
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.plot.region.profiles(rnb.set.example,rnb.sample.groups(rnb.set.example)[[1]],"genes")
## End(Not run)
```

rnb.plot.region.site.density

rnb.plot.region.site.density

Description

Plots the density of sites accross the specified region type

Usage

rnb.plot.region.site.density(rnb.set, region.type, extend.by = 0.33)
**Arguments**

- **rnb.set**
  - RnBSet object

- **region.type**
  - Region type for which the plot should be generated

- **extend.by**
  - A number between 0 and 1 specifying the percentage by which a region is extended in order to capture methylation information before region start and after region end

**Value**

A ggplot2 object for plotting the plot shows the density of sites across the specified region type for all regions of that type from 0 (region start) to 1 (region end). Sites in the flanking areas are also shown (coordinates <0 and >1).

**Author(s)**

Fabian Mueller

**Examples**

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.plot.region.site.density(rnb.set.example,"genes")

## End(Not run)
```

**Description**

Creates a point-and-whisker plots showing beta value distributions at Sentrix positions for the given slide.

**Usage**

```r
rnb.plot.sentrix.distribution(rnb.set, sentrix.id)
```

**Arguments**

- **rnb.set**
  - HumanMethylation450K dataset as an object of type RnBeadSet.

- **sentrix.id**
  - Slide number (Sentrix ID) as an integer or character singleton.

**Value**

Generated point-and-whisker plot (an instance of ggplot) of mean methylations for the samples on the specified slide, or FALSE if the dataset is non-empty but does not contain samples on the given slide. If the provided dataset does not contain valid Sentrix ID and position information (or is an empty dataset), this method returns NULL.
rnb.plot.sentrix.distributions

Description

Creates one or more point-and-whisker plots showing beta value distributions at Sentrix positions.

Usage

rnb.plot.sentrix.distributions(rnb.set, fprefix = "sentrix_whisker", ...)

Arguments

- **rnb.set**: HumanMethylation450K dataset as an object of type `RnBeadSet`.
- **fprefix**: File name prefix to be used in the generated plots. In order to ensure independence of the operating system, there are strong restrictions on the name of the file. See the documentation of `createReportPlot` for more information.
- **...**: Other arguments passed to `createReportPlot`. These can include the named parameters `report`, `width`, `height`, and others.

Details

If no additional parameters are specified, this function creates one PDF and one low-resolution PNG file for every generated plot.

Value

Point-and-whisker plot (an instance of `ReportPlot`), or a list of such plots - one per slide. If the provided dataset does not contain valid Sentrix ID and position information (or is an empty dataset), this method returns `NULL`.

Author(s)

Yassen Assenov

See Also

- `rnb.plot.sentrix.distribution` for creating a single plot for a specified slide number
**rnb.plot.snp.barplot**

Description

Bar plots of beta-values from the genotyping probes

Usage

```
rnb.plot.snp.barplot(rnb.set, sample, writeToFile = FALSE, numeric.names = FALSE, ...)
```

Arguments

- `rnb.set`: RnBeadRawSet or RnBeadSet object
- `sample`: unique sample identifier. In case `rnb.getOption("identifiers.column")` is not NULL, `sample` should attain values from the corresponding column, or `colnames(meth(rnb.set))` otherwise.
- `writeToFile`: flag specifying whether the output should be saved as `ReportPlot`
- `numeric.names`: if TRUE and `writeToFile` is TRUE, substitute the plot options in the plot file name with digits
- `...`: other arguments to `createReportPlot`

Value

plot as an object of type `ReportPlot` if `writeToFile` is TRUE and of class `ggplot` otherwise.

Author(s)

Pavlo Lutsik

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
samp<-samples(rnb.set.example)[1]
rnb.plot.snp.barplot(rnb.set.example, samp)
## End(Not run)
```
rnb.plot.snp.boxplot

Description
Box plots of beta-values from the genotyping probes

Usage
rnb.plot.snp.boxplot(rnb.set, writeToFile = FALSE, ...)

Arguments
rnb.set RnBeadSet object
writeToFile a flag specifying whether the output should be saved as ReportPlot
... other arguments to createReportPlot

Author(s)
Pavlo Lutsik

Examples
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.plot.snp.boxplot(rnb.set.example)
## End(Not run)

rnb.plot.snp.heatmap

Description
Heatmap of beta-values from genotyping probes

Usage
rnb.plot.snp.heatmap(rnb.set, writeToFile = FALSE, ...)

Arguments
rnb.set RnBeadRawSet or RnBeadSet object
writeToFile flag specifying whether the output should be saved as ReportPlot
... other arguments to createReportPlot
Value
plot as an object of type \texttt{ReportPlot} if \texttt{writeToFile} is \texttt{TRUE} and of class \texttt{ggplot} otherwise.

Author(s)
Pavlo Lutsik

Examples
\begin{verbatim}
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.plot.snp.heatmap(rnb.set.example)
## End(Not run)
\end{verbatim}

Description
Gets the supported region annotations for a given genome assembly.

Usage
\begin{verbatim}
rnb.region.types(assembly = "hg19")
\end{verbatim}

Arguments
\begin{itemize}
  \item \texttt{assembly} \hspace{1cm} Genome assembly of interest. See \texttt{rnb.get.assemblies} for the list of supported genomes.
\end{itemize}

Value
Region types supported by \texttt{RnBeads} in the form of a character vector. The built-in ones are "cpgislands", "genes", "promoters" and "tiling". The names of all custom region definitions are also included in the returned vector.

Author(s)
Yassen Assenov

See Also
\texttt{rnb.get.annotation}, \texttt{rnb.set.annotation}

Examples
\begin{verbatim}
## Not run:
"promoters" %in% rnb.region.types() \# TRUE
## End(Not run)
\end{verbatim}
rnb.region.types.for.analysis

Description

Identifies the region types that are summarized by the given dataset and pointed to for analysis.

Usage

rnb.region.types.for.analysis(rnb.set)

Arguments

rnb.set  Methylation dataset as an object of type inheriting RnBSet.

Details

This function intersects the value of the analysis option "region.types" with the region types that are summarized in the provided dataset. In case the option’s value is NULL, this function returns all summarized region types in rnb.set.

Value

List of all region types to be analyzed in the current dataset in the form of a character vector.

Author(s)

Yassen Assenov

See Also

rnb.getOption for checking the value of the "region.types" option; summarized.regions for obtaining the region types summarized in a dataset

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
"promoters" %in% rnb.region.types.for.analysis(rnb.set.example)
## End(Not run)
```
**rnb.remove.annotation**

**Description**
Deletes a region annotation table. Use this function with caution; its operation cannot be undone.

**Usage**
rnb.remove.annotation(type, assembly = "hg19")

**Arguments**
- **type**: One-element character vector giving the name of the region annotation.
- **assembly**: Genome assembly of interest. See rnb.get.assemblies for the list of supported genomes.

**Value**
Invisibly, TRUE if the annotation has been successfully deleted, or FALSE if the specified region type is not supported.

**Author(s)**
Fabian Mueller

**See Also**
rnb.get.annotation, rnb.region.types

**Examples**
```r
## Not run:
t.regions <- rnb.get.annotation("tiling")
rnb.remove.annotation("tiling")
## End(Not run)
```

**rnb.RnBSet.to.bed**

**Description**
convert an RnBSet object to *.bed files.

**Usage**
rnb.RnBSet.to.bed(rnb.set, out.dir, reg.type = "sites", names.quant.meth = TRUE, add.track.line = TRUE, verbose = TRUE)

```r
```
rnb.RnBSet.to.bedGraph

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rnb.set</td>
<td>Object of class RnBSet</td>
</tr>
<tr>
<td>out.dir</td>
<td>output directory. If not existing, it will be created. otherwise files in that directory are overwritten.</td>
</tr>
<tr>
<td>reg.type</td>
<td>region type to be converted</td>
</tr>
<tr>
<td>names.quant.meth</td>
<td>should the names of the bed regions contain information on the methylation level. If TRUE the following format is applied: meth_percent covg(rnb.set) is not NULL</td>
</tr>
<tr>
<td>add.track.line</td>
<td>Add a track line to the bed file to enable browsers like IGV to display the data better</td>
</tr>
<tr>
<td>verbose</td>
<td>More detailed logger output</td>
</tr>
</tbody>
</table>

Details

Details on bed can be found in the UCSC Genome Browser documentation. Each methylation site is an entry in the resulting bed file. The Score column corresponds to a site’s methylation value in the interval [0,1].

Value

(invisibly) a summary list containing information on the conversion step. elements are filenames (a table containing information on which sample has been written to what filename) and assembly (a string indicating the assembly used by rnb.set).

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.RnBSet.to.bed(rnb.set.example,tempdir())
## End(Not run)
```

rnb.RnBSet.to.bedGraph

Description

convert an RnBSet object to *.bedGraph files.

Usage

```r
rnb.RnBSet.to.bedGraph(rnb.set, out.dir, reg.type = "sites")
```
Arguments

- `rnb.set`: Object of class `RnBSet`
- `out.dir`: output directory. If not existing, it will be created. otherwise files in that directory are overwritten.
- `reg.type`: region type to be converted

Details

Details on bedGraph can be found [here](#). Each methylation site is an entry in the resulting bedGraph file. The Score column corresponds to a site’s methylation value in the interval $[0,1]$.

Value

(invisibly) a summary list containing information on the conversion step. elements are filenames (a table containing information on which sample has been written to what filename) and assembly (a string indicating the assembly used by `rnb.set`).

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.RnBSet.to.bedGraph(rnb.set.example,tempdir())
## End(Not run)
```

### Description

convert an `RnBSet` object to a `GRangesList` object

### Usage

```r
rnb.RnBSet.to.GRangesList(rnb.set, reg.type = "sites",
return.regular.list = FALSE)
```

### Arguments

- `rnb.set`: Object of class `RnBSet`
- `reg.type`: region type to be converted
- `return.regular.list`: flag indicating whether a regular `list` object should be returned instead of a `GRangesList`. Might improve performance in some cases
Value

a GRangesList or list object with one list element (GRanges) for each sample in rnb.set

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
result <- rnb.RnBSet.to.GRangesList(rnb.set.example)
```

rnb.run.analysis  RnBeads Analysis Pipeline

Description

Starts the RnBeads analysis pipeline on the given dataset. It loads the dataset if it is specified as a location.

Usage

```r
rnb.run.analysis(dir.reports, data.source = NULL, sample.sheet = NULL, 
data.dir = NULL, GS.report = NULL, GEO.acc = NULL, 
data.type = rnb.getOption("import.default.data.type"), 
initialize.reports = TRUE, build.index = TRUE, save.rdata = TRUE)
```

Arguments

- `dir.reports`: Directory to host the generated report files. This must be a character of length one that specifies either a non-existent path (when `initialize.reports` is `TRUE`), or an existing directory (when `initialize.reports` is `FALSE`). In the latter case, a call to `rnb.initialize.reports` might be required before viewing the reports.
- `data.source`: Methylation dataset as an object of type inheriting RnBSet, or a character vector specifying the location of the data items on disk. The expected length of the vector differs for different values of `data.type`; see `rnb.execute.import` for a more detailed description. If set, the parameters `sample.sheet`, `data.dir`, `GS.report`, `GEO.acc` will be ignored.
- `sample.sheet`: A spreadsheet-like text file with sample annotations. The required columns are different for different values of `data.type`.
- `data.dir`: For `data.type %in% c("data.dir", "idat.dir", "bed.dir")` a character singleton specifying the location of the directory with data files. The directory should have zero depth, i.e. should contain no subdirectories.
- `GS.report`: GenomeStudio report file. `data.type` will be automatically set to "GS.report".
**GEO.acc**
Gene Expression Omnibus accession of the data series with HumanMethylation450 data. `data.type` will be automatically set to "GEO".

**data.type**
character vector of length one specifying the type of the input data. The value must be one of "data.dir", "idat.dir", "GS.report", "GEO" or "rnb.set". See `rnb.execute.import` for a more detailed description.

**initialize.reports**
Flag indicating if the report’s directory must be initialized. If this parameter is set to TRUE, this function attempts to create the path specified by `dir.reports`. Otherwise, `dir.reports` is expected to signify an existing directory.

**build.index**
Flag indicating if a report index file (named "index.html") should be created after all modules in the pipeline complete their analyses. If this is TRUE, the index file is also displayed using the function `rnb.show.report`.

**save.rdata**
Flag indicating whether important data objects (the filtered and unfiltered RnB-Sets, differential methylation) should be saved to an RData file in the reports folder.

**Value**
Invisibly, the loaded, normalized and/or possibly filtered dataset as an object of type inheriting `RnBSet`.

**Author(s)**
Yassen Assenov

**See Also**
RnBeads modules

---

**Description**
Executes the analysis pipeline for an example from the RnBeads web site.

**Usage**
```r
rnb.run.example(index = 4L, dir.output = "example")
```

**Arguments**

- **index**
Example to start. This must be one of 1, 2, 3 or 4.

- **dir.output**
One-element character vector specifying the directory to contain the downloaded data files and generated reports. This must be a non-existent path, as this function attempts to create it.

**Details**
For more information about the examples, please visit the dedicated page on the RnBeads web site.
Value

Invisibly, the loaded, normalized and/or possibly filtered dataset as an object of type inheriting `RnBSet`.

## End(Not run)
```

```

rnb.run.import RnBeads Modules in the Analysis Pipeline

Description

Functions that start the predefined modules in the RnBeads analysis pipeline.

Usage

```
rnb.run.import(data.source,
    data.type = rnb.getOption("import.default.data.type"), dir.reports,
    init.configuration = !file.exists(file.path(dir.reports, "configuration")),
    close.report = TRUE, show.report = FALSE)
```

```
rnb.run.qc(rnb.set, dir.reports,
    init.configuration = !file.exists(file.path(dir.reports, "configuration")),
    close.report = TRUE, show.report = FALSE)
```

```
rnb.run.preprocessing(rnb.set, dir.reports,
    init.configuration = !file.exists(file.path(dir.reports, "configuration")),
    close.report = TRUE, show.report = FALSE)
```

```
rnb.run.inference(rnb.set, dir.reports,
    init.configuration = !file.exists(file.path(dir.reports, "configuration")),
    close.report = TRUE, show.report = FALSE)
```

```
rnb.run.exploratory(rnb.set, dir.reports,
    init.configuration = !file.exists(file.path(dir.reports, "configuration")),
    close.report = TRUE, show.report = FALSE)
```

```
rnb.run.differential(rnb.set, dir.reports,
    init.configuration = !file.exists(file.path(dir.reports, "configuration")),
    close.report = TRUE, show.report = FALSE)
```
```
```
close.report = TRUE, show.report = FALSE)

rnb.run.tnt(rnb.set, dir.reports,
  init.configuration = !file.exists(file.path(dir.reports, "configuration")),
  close.report = TRUE, show.report = FALSE)

Arguments

data.source character vector specifying the location of the data items on disk. The
  expected length of the vector differs for different values of data.type; see
  rnb.execute.import for a more detailed description.
data.type character vector of length one specifying the type of the input data. The
  value of this parameter must be one of "idat.dir", "data.dir", "data.files",
  "GS.report", "GEO" or "rnb.set". See rnb.execute.import for
  a more detailed description.
dir.reports Directory to host the generated report file. Note that if this directory contains
  files, they may be overwritten.
init.configuration Flag indicating if the configuration directory (usually shared among reports)
  should also be created.
close.report Flag indicating if the created report is to be closed using the off
  method.
show.report Flag indicating if the report is to be displayed after it is created. If this is, TRUE
  rnb.show.report is called to open the generated HTML file.
rnb.set Methylation dataset as an object of type inheriting RnBSet.

Details

The functions start the import, quality control, preprocessing, covariate inference, tracks and tables,
exploratory analysis and differential methylation modules, respectively.

Value

For rnb.run.import, rnb.run.preprocessing and rnb.run.inference, the returned value is a list of two elements - the initialized or modified dataset and the created report.
All other functions return the created report, invisibly.

## End(Not run)

---

**rnb.run.xml**

### Description

Starts the analysis pipeline from an XML configuration file. This function uses the XML package to parse the configuration file.

### Usage

```
rnb.run.xml(fname, create.r.command = FALSE)
```

### Arguments

- **fname**: XML configuration file to read.
- **create.r.command**: Flag indicating if the R command(s) that correspond to the given XML configuration should be generated. If this is set to TRUE, a file named "analysis.R" is created in the reports directory.
Details

Two values are required to be specified (as tags) in the configuration file - data.source and dir.reports. They define the input and output directory, respectively. In addition, the file may define analysis option values. The vignette Comprehensive DNA Methylation Analysis with RnBeads describes in details the syntax of the XML configuration file.

The sample annotation table must be stored as a file in data.source. For more information about the required parameters, see the documentation of rnb.run.analysis, which is called by this function.

Value

Invisibly, the loaded, normalized and/or possibly filtered dataset as an object of type inheriting RnBSet.

Author(s)

Yassen Assenov

See Also

rnb.run.analysis for starting an analysis pipeline

Description

Identifies sample subgroups defined in the given annotation information.

Usage

rnb.sample.groups(annotations, columns = NULL, columns.pairs = NULL, min.group.size = rnb.getOption("min.group.size"), max.group.count = rnb.getOption("max.group.count"))

Arguments

annotations Methylation dataset as an object of type inheriting RnBSet, or its sample annotations in the form of a data.frame. If this parameter is a dataset, the annotation information is extracted using the method pheno.

columns Optional; predefined column names (in the form of a character vector) or indices (an integer vector) to consider. All other columns in the annotation table will be ignored.

columns.pairs Optional; a NAMED vector containing for each column name for which paired comparisons should be performed (say columnA) the name or index of another column (say columnB) in which same values indicate the same pairing. columnA should be the name of the value columnB in this vector.

min.group.size Minimum number of samples in each subgroup. This must be a positive integer.
max.group.count

Maximum number of subgroups defined by a trait. This must be an integer greater than 1.

Value

List of traits that define subgroups in the dataset. For each trait, the defined subgroups are represented by a list of integer vectors storing the corresponding sample indices.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
str(rnb.sample.groups(rnb.set.example))
## End(Not run)
```

rnb.sample.replicates

Identifies sample replicates defined in the given sample annotation table.

Description

Usage

```r
rnb.sample.replicates(rnb.set, replicate.id.col)
```

Arguments

- `rnb.set` Methylation dataset as an object of type inheriting `RnBSet`
- `replicate.id.col` Trait (column name in the sample annotation table) that indicates sample replicates. Replicates should have the same value for this trait, while samples without replicates are expected to have unique values or missing values.

Value

List of length of the number of replicates in the dataset. Each element is an integer vector storing the corresponding sample indices.

Author(s)

Fabian Mueller
Description

Creates a sample summary table from an RnBSet object

Usage

rnb.sample.summary.table(rnbSet)

Arguments

rnbSet RnBSet of interest.

Value

a summary table (as data.frame) with the following variables for each sample (rows):

- **sampleName** Name of the sample
- **_*num** (* can be ‘sites’ or a region type)
  
  - Number of sites or regions with coverage in the sample
- **_*covegMean** (RnBiseqSet only)
  
  - Mean coverage of sites or regions in the sample
- **_*covegMedian** (RnBiseqSet only)
  
  - Median coverage of sites or regions in the sample
- **_*covegPerc25** (RnBiseqSet only)
  
  - 25 percentile of coverage of sites or regions in the sample
- **_*covegPerc75** (RnBiseqSet only)
  
  - 75 percentile of coverage of sites or regions in the sample
- **_*numCovg5,10,30,60** (RnBiseqSet only)
  
  - Number of sites or regions with coverage greater or equal to 5,10,30,60
- **sites_numDPval5em2,1em2,1em3** (RnBeadSet only)
  
  - Number of sites with a detection p-value smaller than 0.05,0.01,0.001
- **_*numSitesMean** (** is any region type)
  
  - Mean number of sites in a region
- **_*numSitesMedian**
  
  - Median number of sites in a region
- **_*numSites2,5,10,20**
  
  - Number of regions with at least 2,5,10,20 sites with valid methylation measurements

Author(s)

Fabian Mueller
Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
rnb.sample.summary.table(rnb.set.example)

## End(Not run)
```

Description

Saves the specified region annotation table and its accompanying data structures to a binary file.

Usage

```r
rnb.save.annotation(fname, type, assembly = "hg19")
```

Arguments

- **fname**: One-element character vector giving the name of the file to contain the annotation data. If this file already exists, it will be overwritten.
- **type**: One-element character vector giving the name of the region annotation.
- **assembly**: Genome assembly of interest. See `rnb.get.assemblies` for the list of supported genomes.

Details

This function is used in combination with `rnb.load.annotation` to enable fast reloading of custom region annotations. It can also be used to save a build-in region annotation (e.g. before overwriting it) but not site or control probe annotations.

Author(s)

Yassen Assenov

See Also

- `rnb.load.annotation` for loading a saved annotation
Description

Adds or replaces a region annotation table.

Usage

```
rnb.set.annotation(type, regions, description = NULL, assembly = "hg19")
```

Arguments

- **type**: One-element character vector giving the name of the annotation. If this region type is already available, it will be overwritten for the current session. The type cannot be one of "CpG", "probes450" or "controls450", because these names are reserved for the annotation tables of CpG dinucleotides, and Infinium methylation and control probes, respectively.

- **regions**: BED file defining regions (see Details). Alternatively, the value of this parameter can be a table of genomic regions in the form of a `data.frame`, containing at least the following three columns - "chromosome", "start" and "end" (notice the lower case). The "chromosome" column must be a character or factor vector that lists chromosome names. The "start" and "end" columns are expected to contain genomic positions as integers. The row names of this `data.frame` are used as region identifiers.

- **description**: Optional; short description in the form of a non-empty character vector. The elements in this vector are concatenated without a separator to form the description of the annotation.

- **assembly**: Genome assembly of interest. See `rnb.get.assemblies` for the list of supported genomes.

Details

In case the parameter `regions` specifies an existing BED file, regions are loaded from this file. The number of columns defined must be at least 3. Columns after the sixth one, if present, are dropped. The columns are given the following names: "chromosome", "start", "end", "id", "score" and "strand".

The annotation tables in RnBeads focus on chromosomes "chr1", "chr2", ..., "chr22", "chrX" and "chrY". Regions on other chromosomes are ignored. This function also recognizes the convention of chromosome names such as "1", adopted, for example, by Ensembl. Apart from this, the region definition table is not examined in details by this function; therefore, regions located on unsupported chromosomes or having invalid (e.g. negative) genomic coordinates are simply not mapped to any sites or probes.

`rnb.get.annotation` for extracting annotation; `rnb.region.types` for all loaded region types in a genome assembly

Examples

```r
## Not run:
my.regions <- data.frame(
  chromosome = c("chr1", "chr1"),
  start = c(49242278L, 49242372L),
  end = c(49242590L, 49242810L),
  rownames = c("BEND5E1", "CpG:38"))

txt <- "First exon of the BEND5 gene and an overlapping CpG island."

rnb.set.annotation("my regions", my.regions, txt)
```

## End(Not run)

---

Description

wrapper for `rnb.set.annotation` to accept the region format as output by `annotation(rnb.set)`. Additionally, CpG statistics are added to the annotation.

Usage

```
rnb.set.annotation.and.cpg.stats(type, regions, description = NULL,
  assembly = "hg19")
```

Arguments

- `type`, `description`, `assembly`
  Parameters handled exactly as in `rnb.set.annotation`

- `regions`
  a data.frame handled similarly as by `rnb.set.annotation` with the exception that the genomic location columns should be specified using upper case first letters

Author(s)

Fabian Mueller

See Also

`rnb.set.annotation`
rnb.show.report

Description

Opens the given HTML report file in the browser.

Usage

rnb.show.report(report)

Arguments

report Report object to open.

Author(s)

Pavlo Lutsik

rnb.step.betadistribution

Description

Computes the distributions of beta values across various sample groups and adds a corresponding section to the report.

Usage

rnb.step.betadistribution(rnb.set, report, columns = rnb.getOption("exploratory.columns"), points.per.group = rnb.getOption("distribution.subsample"))

Arguments

rnb.set HumanMethylation450K dataset as an object of type RnBSet.
report Report to contain the methylation deviation section. This must be an object of type Report.

columns Optional; predefined column names (in the form of a character vector) or indices (an integer vector) in the sample annotation table. Only these columns are considered for grouping samples and defining profiles. All other columns in the phenotype table are ignored.

cpyoints.per.group the targeted number of points (T) per group. Set this to a value < 1 to disable subsampling. More information in the Details section

Value

The modified report.
Details

If subsampling is enabled (i.e. \texttt{points.per.group}>0), observations per group are subsampled according to the following procedure: Given \( K \) groups and numbers of observed beta values per group \( N_1, \ldots, N_K \), and the target number of points per group \( T \): the total number of points \( N = \sum(N_1, \ldots, N_K) \) is computed Afterwards the proportions \( p_k = \frac{N_k}{N} \) is computed and from each group, \( S_k = p_k \times (K \times T) \) observations are randomly selected from all observations belonging to group \( k \).

Author(s)

Fabian Mueller

Description

Writes a table to a file. Different formats and compression options are available.

Usage

\texttt{rnb.write.table(tt, fname, fpath = "", format = "csv", gz = FALSE, \ldots)}

Arguments

\begin{itemize}
\item \texttt{tt} Table to be written to file, usually in the form of a \texttt{matrix} or \texttt{data.frame}.
\item \texttt{fname} Target file name. If this file already exists, it will be overwritten.
\item \texttt{fpath} Target file path. If "" (default value), \texttt{fname} is assumed to contain the absolute path.
\item \texttt{format} Target format; one of "csv", "tab" or "txt", denoting comma-separated, tab-separated and default text format, respectively. The last format allows for a user-specified delimiter through an additional parameter \texttt{sep}. See the documentation of \texttt{write.table} for more details.
\item \texttt{gz} Flag indicating whether the file should be zipped in \texttt{gz} format.
\item \texttt{\ldots} Any additional arguments to be passed on to \texttt{write.table} or \texttt{utils::write.csv}.
\end{itemize}

Value

The (possibly updated) target file name, invisibly. If \texttt{gz} is \texttt{TRUE}, the string ".gz" will be appended to \texttt{fname}.

Author(s)

Fabian Mueller

See Also

\texttt{write.table}
rnb.xml2options

Examples

```r
## Not run:
data(mtcars)
rnb.write.table(mtcars,tempfile(pattern="cars",fileext=".csv"))
## End(Not run)
```

Description

Parses and partially validates parameters and RnBeads options from an XML tree.

Usage

```r
rnb.xml2options(fname, return.full.structure = FALSE)
```

Arguments

- `fname` File name containing the XML analysis option values. The name of the root node in this document must be "rnb.xml".
- `return.full.structure` if enabled, return the full structure instead of just the option list

Value

List of two sublists - "analysis.params" and "options", storing the specified analysis parameters and previous values of the RnBeads options, respectively.

Author(s)

Yassen Assenov

Examples

```r
## Not run:
fname <- paste0("extdata/optionProfiles/",profile,".xml")
rnb.xml2options(system.file(fname,package="RnBeads"))
## End(Not run)
```
RnBClusterRun-class

**RnBClusterRun Class**

**Description**

A class for configuring and running RnBeads on a scientific compute cluster.

**Slots**

- **architecture** A `ClusterArchitecture` object managing the settings for a scientific compute cluster.
- **modules** A vector of pipeline modules.
- **module.res.req** Stores the resource requirements for each module. A list containing named vectors for the resources.
- **module.num.cores** Stores the number of cores for each module.

**Methods**

- `setModuleResourceRequirements`, `RnBClusterRun`, `character`, `character-method` Sets the resource requirements for the different pipeline modules.
- `setModuleNumCores`, `RnBClusterRun`, `integer`, `character-method` Sets the number of cores used by the different pipeline modules.
- `getModuleNumCores`, `RnBClusterRun-method` Gets the number of cores used by the different pipeline modules.
- `run`, `RnBClusterRun-method` Submit the pipeline modules to the cluster.

**Author(s)**

Fabian Mueller

RnBDiffMeth-class

**RnBDiffMeth Class**

**Description**

A class for storing differential methylation data.

**Details**

Contains differential methylation tables (DMT) for multiple comparisons and region types. DMTs can be stored in memory as R objects or on disk.
Slots

- **sites**: List of differential methylation tables on site level (see `computeDiffMeth.bin.site` for details). Indexed by comparison.
- **regions**: List of lists of differential methylation tables on region levels (see `computeDiffMeth.bin.region` for details). Indexed by region type on the top level and comparison on the lower level.
- **comparisons**: Character vector of all comparisons stored in the objects. Vector indices correspond to indices in the `sites` and `regions` list slots.
- **region.types**: Character vector of all region types stored in the objects. Vector indices correspond to indices in the `regions` list slot.
- **comparison.grouplabels**: A character matrix with 2 columns containing group labels of all comparisons in the object.
- **comparison.info**: A list containing comparison information for each comparison. See `get.comparison.info` for details.
- **site.test.method**: Method which was applied to obtain the site-level p-values.
- **covg.thres**: Coverage threshold. Important for certain columns of the differential methylation tables. See `computeDiffMeth.bin.site` and `computeDiffMeth.bin.region` for details.
- **disk.dump**: Flag indicating whether the tables should be stored on disk rather than in the main memory.
- **disk.path**: Path on the disk for DMTs. Only meaningful if `disk.dump` is TRUE.

Methods

- `destroy,RnBDiffMeth-method`: Remove tables stored to disk from the file system.
- `get.region.types,RnBDiffMeth-method`: Gets all region types represented in the object as a character vector.
- `get.comparisons,RnBDiffMeth-method`: Gets all comparisons represented in the object as a character vector.
- `get.comparison.grouplabels,RnBDiffMeth-method`: Gets all comparison group names as a matrix.
- `get.covg.thres,RnBDiffMeth-method`: Gets the coverage threshold employed for obtaining statistics in the differential methylation tables.
- `get.table,RnBDiffMeth-method`: Gets a differential methylation table.
- `addDiffMethTable,RnBDiffMeth-method`: Adds a differential methylation table.
- `reload,RnBDiffMeth-method`: Relink disk dumped tables. Useful if the files are manually copied or if the object is loaded again.
- `save.tables,RnBDiffMeth-method`: Save disk dumped tables as binaries and zip them. Useful if the files are copied or shared.
- `join.diffMeth`: Merges two disjoint `RnBDiffMeth` objects into one.

Author(s)

Fabian Mueller
**RnBeadClustering-class**

**RnBeadClustering Class**

### Description

Storage class for the results of a clustering algorithm applied on an `RnBSet` dataset.

### Slots

- **dissimilarity** Dissimilarity metric used in the form of a one-element character vector.
- **dimensionality** Dimensionality of the clustered points in the form of a one-element integer vector.
- **algorithm** Clustering algorithm (and optionally, type) as a character vector of length 1 or 2.
- **result** Resulting object after applying the clustering algorithm on a dataset.
- **assignments** Cluster assignments for the samples in the dataset as a matrix. Row names in this matrix are sample identifiers, and each column is dedicated to partitioning into $k$ clusters for a fixed $k$.
- **silhouettes** numeric vector of mean silhouette values for each tested value of $k$.

### Methods and Functions

- **samples** Gets the identifiers of all samples used in the clustering.

### Author(s)

Yassen Assenov

---

**RnBeadRawSet-class**

**RnBeadRawSet-class**

### Description

Main class for storing HumanMethylation micorarray data which includes intensity information

Wrapper function `.RnBeadRawSet`

### Usage

```r
RnBeadRawSet(pheno, probes, M, U, M0 = NULL, U0 = NULL, 
  bead.counts.M = NULL, bead.counts.U = NULL, p.values = NULL, 
  qc = NULL, platform = "450k", beta.offset = 100, 
  summarize.bead.counts = TRUE, summarize.regions = TRUE, 
  region.types = rnb.region.types.for.analysis("hg19"), 
  useff = rnb.getOption("disk.dump.big.matrices"), ffcleanup = FALSE)
```
**Arguments**

- **pheno**
  Phenotypic data.
- **probes**
  Character vector of Infinium(R) probe identifiers
- **M**
  Matrix of intensities for the probes measuring the abundance of methylated molecules
- **U**
  Matrix of intensities for the probes measuring the abundance of unmethylated molecules
- **M0**
  Matrix of "out-of-band" intensities for the probes measuring the abundance of methylated molecules
- **U0**
  Matrix of "out-of-band" intensities for the probes measuring the abundance of unmethylated molecules
- **bead.counts.M**
  Matrix of bead counts per probe.
- **bead.counts.U**
  Matrix of bead counts per probe.
- **p.values**
  Matrix of detection p-values.
- **qc**
  ...
- **platform**
  Character singleton specifying the microarray platform: "450k" corresponds to HumanMethylation450 microarray, and "27k" stands for HumanMethylation27.
- **beta.offset**
  A regularization constant which is added to the denominator at beta-value calculation
- **summarize.bead.counts**
  If TRUE the coverage slot is filled by summarizing the bead.counts.M and bead.counts.U matrices. For type I probes the summarization is done using min operation, while for type II probes the bead counts should be identical in both supplied matrices
- **summarize.regions**
  ...
- **region.types**
  A character vector specifying the region types, for which the methylation information will be summarized.
- **useff**
  If TRUE the data matrices will be stored as ff objects
- **ffcleanup**
  If TRUE and disk dumping has been enabled the data of the input ff objects will be deleted

**Slots**

- **pheno**
  Phenotypic data.
- **M**
  Matrix of intensities for the probes measuring the abundance of methylated molecules.
- **U**
  Matrix of intensities for the probes measuring the abundance of unmethylated molecules.
- **M0**
  Matrix of "out-of-band" intensities for the probes measuring the abundance of methylated molecules.
- **U0**
  Matrix of "out-of-band" intensities for the probes measuring the abundance of unmethylated molecules.
- **bead.counts.M**
  Matrix of bead counts per probe.
- **bead.counts.U**
  Matrix of bead counts per probe.
Methods and Functions

- **samples** Gets the identifiers of all samples in the dataset.
- **M** Get the matrix of intensities for the probes measuring the abundance of methylated molecules.
- **U** Get the matrix of intensities for the probes measuring the abundance of unmethylated molecules.
- **intensities.by.color** Get probe intensities in each color channel.

Author(s)

Pavlo Lutsik

---

RnBeads data

**Description**

RnBeads facilitates comprehensive analysis of various types of DNA methylation data at the genome scale. It extends previous approaches for such analysis by high throughput capabilities, as well as presenting results in a comprehensive, highly interpretable fashion.

**Details**

The complete analysis can be performed by calling the function `rnb.run.analysis`.

**References**

---

**RnBeads.data**

**RnBeads Annotation Tables**

**Description**

RnBeads uses sets of annotation tables and mappings (from regions to sites) for each of the supported genomes. The structures for one assembly are stored in a separate dedicated data package. Currently, the following assemblies are supported:

- "hg19" through the package **RnBeads.hg19**
- "mm10" through the package **RnBeads.mm10**
- "mm9" through the package **RnBeads.mm9**
- "rn5" through the package **RnBeads.rn5**
Format

- **list of four elements** - "regions", "sites", "controls" and "mappings". These elements are described below.

- "regions" list of NULLs; the names of the elements correspond to the built-in region annotation tables. Once the default annotations are loaded, the attribute "builtin" is a logical vector storing, for each region annotation, whether it is the default (built-in) or custom.

- "sites" list of NULLs; the names of the elements correspond to the site and probe annotation tables.

- "controls" list of NULLs; the names of the elements correspond to the control probe annotation tables. The attribute "sites" is a character vector pointing to the site annotation that encompasses the respective control probes.

- "mappings" list of NULLs; the names of the elements correspond to the built-in region annotation tables.

Details

The assembly-specific structures are automatically loaded upon initialization of the annotation, that is, by the first valid call to any of the following functions: `rnb.get.chromosomes`, `rnb.get.annotation`, `rnb.set.annotation`, `rnb.get.mapping`, `rnb.annotation.size`. Adding an annotation amounts to attaching its table(s) and mapping structures to the scaffold.

Author(s)

Yassen Assenov

---

**Description**

Stores the preprocessed information from HumanMethylation experiments

**Usage**

```r
RnBeadSet(pheno, probes, betas, p.values = NULL, bead.counts = NULL,
qc = NULL, platform = "450k", summarize.regions = TRUE,
region.types = rnb.region.types.for.analysis("hg19"),
useff = rnb.getOption("disk.dump.big.matrices"))
```

**Arguments**

- **pheno** Phenotypic data.
- **probes** character vector of Infinium(R) probe identifiers
- **betas** matrix or ff_matrix of beta values. If `probes` are missing should contain Infinium probe identifiers as row names.
- **p.values** matrix or ff_matrix of detection p-values.
- **bead.counts** ...
RnBeadSet-class

qc
plateform character singleton specifying the microarray platform: "450k" corresponds to HumanMethylation450 microarray, and "27k" stands for HumanMethylation27.

summarize.regions

region.types A character vector specifying the region types, for which the methylation information will be summarized.

useff If TRUE the data matrices will be stored as ff objects

Details

There are multiple ways to create an object of type RnBeadSet:

Loading from files Dataset can be loaded from text or binary files. See the function rnb.execute.import for more details.

Downloading from GEO See the function read.geo for details.

Converting from MethyLumiSet ...

Slots

pval.sites matrix of detection p-values with the same dimensions as betas, or NULL if the detection p-values are not available.

pval.regions list of methylation matrix objects, one per available region type. Every row in a matrix corresponds to a methylation site, and every column - to a sample.

covg.sites matrix of bead counts per probe with the same dimensions as betas, or NULL if this data are not available.

qc Quality control probe information in the form of a list of two elements - "Cy3" and "Cy5", storing intensities of probes on the green and red channels, respectively. This slot’s value is NULL if no control probe information is available.

Methods and Functions

samples Gets the identifiers of all samples in the dataset.

pheno Gets the phenotypic and processing data of the dataset.

meth Gets the matrix of methylation beta-values of the dataset.

dpval Gets the matrix of detection p-values of the dataset.

covg Gets the matrix of bead counts of the dataset.

qc Gets the intensities of the quality control probes.

remove.sites Removes probes from the dataset.

remove.samples Removes samples from the dataset.

combine Combines two datasets.

Author(s)

Pavlo Lutsik
RnBiseqSet-class

RnBiseqSet Class

Description
A class for storing the DNA methylation and quality information from bisulfite sequencing experiments

Wrapper function RnBiseqSet

Usage
RnBiseqSet(pheno, sites, meth, covg = NULL, assembly = "hg19", target = "CpG", summarize.regions = TRUE, region.types = rnb.region.types.for.analysis(assembly), useff = rnb.getOption("disk.dump.big.matrices"), verbose = FALSE)

Arguments
- pheno pheno
typic data.
- sites sites CpG site definition, as a data.frame with 3 variables: chromosome (of type character), position (integer) and strand (character, one of "+", "-" or "*"
- meth meth summarized methylation calls as a matrix or ff_matrix
- covg covg read coverage information as a matrix or ff_matrix
- assembly assembly the genome assembly
- target target target DNA methylation features (CpG sites)
- summarize.regions summarize.regions
- region.types region.types region annotations for which the methylation data should be summarized
- useff useff flag specifying whether the ff functionality should be used
- verbose verbose flag specifying whether the diagnostic messages should be written to the console or to the RnBeads logger, if the latter is initialized

Details
TBA

Slots
- status status Normalization status.

Methods and Functions
- combine combine Combines two datasets.

Author(s)
Pavlo Lutsik
RnBSet-class  

**Description**

Basic class for storing DNA methylation and experimental quality information.

**Details**

It is a virtual class and objects of type RnBSet should not be instantiated. Instead, the child classes are used: RnBeadRawSet and RnBeadSet for Infinium HumanMethylation and RnBiseqSet for bisulfite sequencing data.

**Slots**

- `pheno` Sample annotations (phenotypic and processing data) in the form of a `data.frame`.
- `sites` A `matrix` object storing the identifiers of the methylation sites for which the methylation information is present.
- `meth.sites` Matrix of methylation values. Every row corresponds to a methylation site, and every column - to a sample.
- `covg.sites` Matrix of coverage values. Every row corresponds to a methylation site, and every column - to a sample.
- `regions` List of all identifiers of methylation sites for which methylation information is available.
- `meth.regions` List of methylation `matrix` objects, one per available region type. Every row in a `matrix` corresponds to a methylation site, and every column - to a sample.
- `covg.regions` List of coverage `matrix` objects, one per available region type. Every row corresponds to a region, and every column - to a sample.
- `status` List with meta-information about the object.
- `assembly` Character vector of length one, specifying the genome assembly which the object is linked to, e.g. "hg19".
- `target` Character vector of length one, specifying the feature class: "CpG" for sequencing data, "probes450" and "probes27" for HumanMethylation450 and HumanMethylation27 microarrays respectively.
- `inferred.covariates` List with covariate information. Can contain elements "sva" and "cell.types".
- `version` Package version in which the dataset was created.

**Methods and Functions**

- `pheno` Gets the phenotypic and processing data of the dataset.
- `samples` Gets the identifiers of all samples in the dataset.
- `summarized.regions` Gets the genomic annotations for which methylation data is present.
- `meth` Gets a `matrix` of methylation values in the dataset.
- `mval` Gets a `matrix` of M values in the dataset.
- `covg` Gets the `matrix` of coverage values of the dataset.
**remove.sites** Removes sites from the dataset.

**remove.samples** Removes samples from the dataset.

**addPheno,RnBSet-method** Add sample annotation to the dataset.

**combine** Combines two datasets.

**regionMapping,RnBSet-method** Retrieve the sites mapping to a given region type

**rnb.sample.summary.table** Creates a sample summary table from an RnBSet object.

**Author(s)**

Pavlo Lutsik

---

**Description**

performs a two-sided t-test for paired samples on each row of a matrix X with the indices `inds.1` vs indices `inds.g2` as group assignments.

**Usage**

```r
callOneSampleTP(X, mu = 0, alternative = "two.sided")
```

**Arguments**

- **X**: Matrix on which the test is performed for every row
- **mu**: The mean that is tested against
- **alternative**: Testing alternative. Must be one of "two.sided" (default), "less", "greater" or "all". In case of "all" a data frame with corresponding alternative variables is returned. Otherwise the result is a vector.

**Value**

vector (or data.frame if alternative=="all") of p-values from a paired t-test

**Note**

Requires `matrixStats` package

**Author(s)**

Fabian Mueller

**Examples**

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
meth.mat <- meth(rnb.set.example)
p.vals <- rowOneSampleTP(meth.mat,mu=0,alternative="greater")
## End(Not run)
```
Description

performs a two-sided t-test for paired samples on each row of a matrix X with the indices inds.1 vs indices inds.g2 as group assignments.

Usage

rowPairedTP(X, inds.g1, inds.g2 = -inds.g1, alternative = "two.sided")

Arguments

- **X**
  Matrix on which the test is performed for every row
- **inds.g1**
  column indices of group 1 members. length(inds.g1)==length(inds.g2) has to hold true.
- **inds.g2**
  column indices of group 2 members. length(inds.g1)==length(inds.g2) has to hold true.
- **alternative**
  Testing alternative. Must be one of "two.sided" (default),"less","greater" or "all". in case of "all" a data frome with corresping alternative variables is returned. Otherwise the result is a vector.

Value

vector (or data.frame if alternative=="all") of p-values from a paired t-test

Note

Requires matrixStats package

Author(s)

Fabian Mueller

Description

performs a two-sided Welch’s t-test (unequal variances, unequal sample sizes) on each row of a matrix X with the indices inds.1 vs indices inds.g2 as group assignments.

Usage

rowWelchP(X, inds.g1, inds.g2 = -inds.g1, na.rm = FALSE, alternative = "two.sided")
Arguments

- **X**: Matrix on which the test is performed for every row
- **inds.g1**: Column indices of group 1 members
- **inds.g2**: Column indices of group 2 members
- **na.rm**: Should NAs be removed (logical)
- **alternative**: Testing alternative. Must be one of "two.sided" (default), "less", "greater" or "all". In case of "all" a data frame with corresponding alternative variables is returned. Otherwise the result is a vector.

Value

Vector (or data.frame if alternative=="all") of p-values resulting from the Welch's t-test

Note

Requires `matrixStats` package

Author(s)

Fabian Mueller

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
meth.mat <- meth(rnb.set.example)
sample.groups <- rnb.sample.groups(rnb.set.example)[[1]]
p.vals <- rowWelchP(meth.mat,sample.groups[[1]],sample.groups[[2]])
## End(Not run)
```

Description

Runs the analysis by submitting jobs for each module to the compute cluster

Usage

```r
## S4 method for signature 'RnBClusterRun'
run(rnb.cr, analysis.id, config.xml, 
    split.differential = TRUE, dry.run = FALSE, long.cmd.thres = 1024L)
```
samples,RnBSet-method

Arguments

- rnb.cr: RnBClusterRun object
- analysis.id: analysis id. used for naming submitted jobs and log files
- config.xml: XML file specifying the analysis options and parameter settings
- split.differential: flag indicating whether to split the differential methylation module into separate jobs according to sample annotation column and region type.
- dry.run: Prevent the actual job submission. Rather only write to a shell script file
- long.cmd.thres: commands that are longer than this number will be encapsulated in shell scripts rather than being submitted as direct command

Value

Nothing of importance

Author(s)

Fabian Mueller

Examples

```r
## Not run:
#specify the xml file for your analysis
xml.file <- "MY_ANALYSIS_SETTINGS.XML"
#set the cluster architecture specific to your environment
arch <- new("ClusterArchitectureSGE")
rnb.cr <- new("RnBClusterRun",arch)
#set up the cluster so that 32GB of memory are required (SGE resource is called "mem_free")
rnb.cr <- setModuleResourceRequirements(rnb.cr,c(mem_free="32G"),"all")
#set up the cluster to use 4 cores on each node for all modules
rnb.cr <- setModuleNumCores(rnb.cr,4L,"all")
#set up the cluster to use 2 cores for the exploratory analysis module
rnb.cr <- setModuleNumCores(rnb.cr,2L,"exploratory")
#run the actual analysis (remove dry.run=TRUE, to really submit the jobs)
run(rnb.cr, "rnbeads_analysis", xml.file, dry.run=TRUE)
## End(Not run)
```

samples,RnBSet-method

samples-methods

Description

Extracts sample identifiers
Usage

```r
## S4 method for signature 'RnBSet'
samples(object)

## S4 method for signature 'RnBeadClustering'
samples(object)
```

Arguments

- `object`: Dataset of interest.

Details

The column of the sample annotation table which contain identifiers is globally controlled via the "identifiers.column" option. In case the latter is `NULL` column names of the matrix returned by the `meth` method are treated as sample identifiers. In case the latter are also missing, a character vector with sample numbers is returned.

Value

character vector of sample identifiers.

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
samples(rnb.set.example)
## End(Not run)
```

Description

save an `RnBDiffMeth` object to disk

Usage

```r
save.rnb.diffmeth(object, path)
```

Arguments

- `object`: `RnBDiffMeth` object
- `path`: path on the disk to save to.

Author(s)

Fabian Mueller
save.rnb.set

Description

Consistent saving of an RnBSet objects with large matrices of type ff.

Usage

\texttt{save.rnb.set(object, path, archive = TRUE)}

Arguments

\begin{itemize}
  \item \texttt{object} RnBSet-inheriting object.
  \item \texttt{path} the name of the output file (or directory if \texttt{archive} is \texttt{FALSE}) without an extension. If only the file name is given the object will be saved in the current working directory.
  \item \texttt{archive} if \texttt{TRUE} (default value) the output is a ZIP-file.
\end{itemize}

Details

The saved object can be reloaded with the \texttt{load.rnb.set} function.

Value

invisibly, the full path to the ZIP file (if \texttt{archive} is \texttt{TRUE}), or to the output directory (otherwise)

Author(s)

Pavlo Lutsik

save.tables,RnBDiffMeth-method

Description

save the disk dumped tables to an \texttt{ff} archive for later reloading

Usage

\# S4 method for signature 'RnBDiffMeth'
\texttt{save.tables(object, file)}

Arguments

\begin{itemize}
  \item \texttt{object} \texttt{RnBDiffMeth} object
  \item \texttt{file} path on the disk to save to.
\end{itemize}
set.covariates.ct

Value

success

Author(s)

Fabian Mueller

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
dm <- rnb.execute.computeDiffMeth(rnb.set.example, pheno.cols=c("Sample_Group","Treatment"),
save.tables(dm,tempfile())
## End(Not run)

set.covariates.ct

Description

Adds the results of cell type estimation to an RnBSet

Usage

set.covariates.ct(rnb.set, ct.obj)

Arguments

rnb.set The RnBSet object to which the results should be added
ct.obj An object of class CellTypeInferenceResult returned by rnb.execute.ct.estimation

Value

The modified RnBSet.

set.covariates.sva

Description

Adds the results of Surrogate Variable Analysis (SVA) to an RnBSet

Usage

set.covariates.sva(rnb.set, sva.obj)
Arguments

rnb.set The RnBSet object to which the results should be added
sva.obj An object of class SvaResult as returned by rnb.execute.sva.

Value

The modified RnBSet. Note that the association information will not be stored.

Author(s)

Fabian Mueller

Examples

## Not run:
library(RnBeads.hg19)
data(small.example.object)
logger.start(fname=NA)
sva.obj <- rnb.execute.sva(rnb.set.example,c("Sample_Group","Treatment"),numSVmethod="be")
sva.obj$sva.performed
sva.obj$num.components
rnb.set.mod <- set.covariates.sva(rnb.set.example, sva.obj)
has.covariates.sva(rnb.set.example,"Sample_Group")
has.covariates.sva(rnb.set.mod,"Sample_Group")

## End(Not run)

setExecutable,ClusterArchitecture,character,character-method

Description

Tells the cluster architecture about an executable that can be submitted as job

Usage

## S4 method for signature 'ClusterArchitecture,character,character'
setExecutable(object,
exec.name, exec.loc)

Arguments

object ClusterArchitecture object
exec.name A name/identifier that will be associated with the given executable
exec.loc The executable’s location

Value

The modified object

Author(s)

Fabian Mueller
setModuleNumCores, RnBClusterRun, integer, character-method

Description
Specifies the number of cores used by the different pipeline modules

Usage
## S4 method for signature 'RnBClusterRun, integer, character'
setModuleNumCores(object, num.cores, 
modules = "all")

Arguments
- **object**: RnBClusterRun object
- **num.cores**: an integer specifying the number of cores to be used
- **modules**: vector of applicable pipeline modules. Can be "all" to specify all modules

Value
The modified object

Author(s)
Fabian Mueller

setModuleResourceRequirements, RnBClusterRun, character, character-method

Description
Specifies resource requirements for the different pipeline modules

Usage
## S4 method for signature 'RnBClusterRun, character, character'
setModuleResourceRequirements(object, 
resources, modules = "all")

Arguments
- **object**: RnBClusterRun object
- **resources**: A NAMED character vector containing the resource requirements as value and the resource name as name
- **modules**: vector of applicable pipeline modules. Can be "all" to specify all modules
## sites,RnBSet-method

### Description

Methylation sites object information for which is present in the RnBSet object.

### Usage

```r
## S4 method for signature 'RnBSet'
sites(object)
```

### Arguments

- `object` Dataset of interest.

### Value

A matrix of type `integer` describing the sites, information for which is present in the object.

### Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
sites(rnb.set.example)
## End(Not run)
```

## summarize.regions,RnBSet-method

### Description

Summarize DNA methylation information for which is present in the RnBSet object.

### Usage

```r
## S4 method for signature 'RnBSet'
summarize.regions(object, region.type, aggregation = rnb.getOption("region.aggregation"), overwrite = TRUE)
```
Arguments

object

Dataset of interest.

region.type

Type of the region annotation for which the summarization will be performed or "strands" for summarizing the methylation values from both strands.

aggregation

Operation to summarize the methylation values. Currently supported values are "mean", "median", "min", "max" and "coverage.weighted".

overwrite

If TRUE the existing region-level information for region.type is discarded.

Value

object of the same class as the supplied one containing the summarized methylation information for the specified region types.

Examples

```
## Not run:
library(RnBeads.hg19)
data(small.example.object)
rnb.set.summarized<-summarize.regions(rnb.set.example, "genes", overwrite=TRUE)
head(meth(rnb.set.summarized, type="genes", row.names=TRUE))
```

## End(Not run)

summarized.regions,RnBSet-method

Description

Gets the genomic annotations for which methylation data is present in the RnBSet object.

Usage

```
## S4 method for signature 'RnBSet'
summarized.regions(object)
```

Arguments

object

Methylation dataset of interest.

Value

character vector listing all genomic annotations summarized in the given dataset. If the dataset contains methylation in sites only, an empty vector is returned.

Author(s)

Yassen Assenov
See Also

- `summarize.regions` for calculating region-wise methylation in a dataset;
- `rnb.set.annotation` for adding or replacing a region annotation table.

Examples

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
summarized.regions(rnb.set.example)

## End(Not run)
```

---

### U.RnBeadRawSet-method

#### U-methods

**Description**

Extract raw unmethylated probe intensity from an object of `RnBeadRawSet` class.

**Usage**

```r
## S4 method for signature 'RnBeadRawSet'
U(object, row.names = FALSE)
```

**Arguments**

- `object`: Dataset of interest.
- `row.names`: Flag indicating whether the resulting matrix will be assigned row names.

**Value**

- `matrix` of the unmethylated probe intensities.

**Examples**

```r
## Not run:
library(RnBeads.hg19)
data(small.example.object)
U.intensity<-U(rnb.set.example)
head(U.intensity)

## End(Not run)
```
**updateRegionSummaries, RnBSet-method**

*updateRegionSummaries*

**Description**

Updates the region information present in an RnBSet by invoking summarize.regions on all region types present in the object.

**Usage**

```r
## S4 method for signature 'RnBSet'
updateRegionSummaries(object)
```

**Arguments**

- `object` Dataset of interest.

**Value**

Sample annotation information available for the dataset in the form of a data.frame.
